VANDERVORT COMB FOUNDATION MILLS.

Send for samples and reduced price list.

2tfdb JNO. VANDERVORT, Laceyville, Pa.

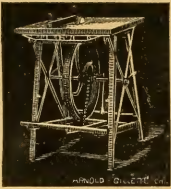
Cash for Beeswax!

Will pay 20c per lb. cash, or 25c in trade for any quantity of good, fair, average beeswax, delivered at our R. R. station. The same will be sold to those who wish to purchase, at 28c per lb., or 35c for *best selected wax*.

Unless you put your name *on the box*, and notify us by mail of amount sent. I can not hold myself responsible for mistakes. It will not pay as a general thing to send wax by *express*.

A. I. ROOT, Medina, Ohio.

Barnes' Foot-Power Machinery.

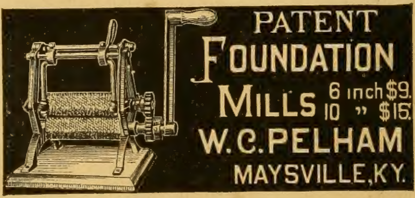


ARNOLD GILLETT CO.

Read what J. I. PARENT, of CHARLTON, N. Y., says — "We cut with one of your Combined Machines last winter 50 chaff hives with 7 inch cap, 100 honey racks, 500 broad frames, 2,000 honey-boxes and a great deal of other work. This winter we have double the amount of bee hives, etc., to make and we expect to do it all with this Saw. It will do all you say it will." Catalogue and Price List Free. Address W. F. & JOHN BARNES, 68 Ruby St., Rockford, Ill.

When more convenient, orders for Barnes' Foot-Power Machinery may be sent to me. A. I. ROOT.

5tfd



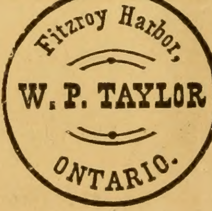
PATENT FOUNDATION MILLS 6 inch $9. 10 " $15.

W. C. PELHAM

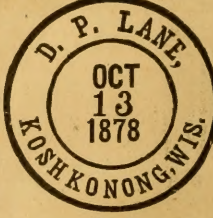
MAYSVILLE, KY.

RUBBER STAMPS

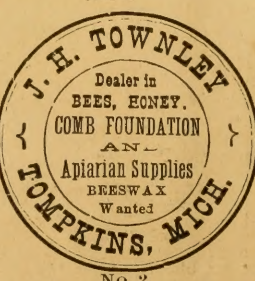
DATING, ADDRESSING, BUSINESS, LETTER HEADS, ETC.



No. 1.



No. 3.



No. 2.

Address only, like No. 1, $1.50; with business card, like No. 2, $2.00; with movable months and figures for dating, like No. 3, $3.00. Full outfit included—pads, ink, box, etc. Sent by mail postpaid. Without ink and pads, 50 cts. less.

Put your stamp on every card, letter, paper, book, or anything else that you may send out by mail or express and you will save yourself and all who do business with you a "world of trouble." I know, you see.

We have those suitable for druggists, grocerymen, hardware dealers, dentists, etc. Send for circular. A. I. ROOT, Medina, O.

CATALOGUES RECEIVED FOR 1886.

G. B. Lewis & Co., Watertown, Wis., send us an 18-page catalogue, fully illustrated; specialties, bee-hives and section boxes.

Smith & Goodell, Rock Falls, Ill., send an 8-page circular; specialties, hives and section boxes.

We have just printed for P. L. Viallon, Bayou Goula, La., a 4-page supplemental catalogue, containing changes since his catalogue for 1885 was sent out.

For J. D. Rusk, Milwaukee, Wis., we have just printed a 4-page list of bee-supplies.

As we go to press we are printing for G. W. Stanley & Bro., Wyoming, N. Y., a one-page circular, GLEANINGS size, relative to their automatic extractor, and smokers.

For F. Boomhower, Gallupville, N. Y., we are also printing a 12-page list of hives, sections, etc.

FOR SALE. Five pair fine Pekin ducks, at $4.00 per pair.
1tfdb D. D. FARNSWORTH, Clive, Polk Co., Iowa.

FOR SALE.—2000 lbs. of extracted honey, in kegs of 160 lbs. each. Quality of honey first class. I will deliver, freight paid, to parties within 800 miles for 8 and 9 cts. per lb. CHAS. T. GEROULD,
East Smithfield, Bradford Co., Pa.

Recent Additions to the Counter Store.

Postage.] [Pr. of 10, of 100

TEN-CENT COUNTER.

9 | SCRAP-ALBUM. Size, 9x11, 12 pages...... | 80 | 7 50

These neatly made scrap-books are getting to be quite a plaything for the children, and they may be made quite convenient and instructive for the older people. I use one for clipping such articles as I want to preserve from the various agricultural papers, and have them safe and secure; and the book is a handsome piece of furniture, even if it does cost only a dime.

FIFTY-CENT COUNTER.

10 | BUTCHER-KNIFE. J. Russell & Co.'s best hand-forged steel. Blade 9 in. long.. | 4 00 | 35 00

A. I. ROOT, Medina, Ohio.

For Sale. Two steam-engines. The two engines advertised on page 808, issue for Dec. 1, are not sold up to date. The engines must be sold. How much do I hear bid? Engines are all in good running order. I will pay freight one way to any one who will come and buy one or both of said engines. J. B. MURRAY,
1d Ada, Hardin Co., Ohio.

DADANT'S FOUNDATION FACTORY, WHOLESALE and RETAIL. See advertisement in another column. 3btfd

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per year, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—The market for comb honey in this city is very inactive, which we attribute to the continued warm weather, in consequence of which, prices are gradually shading. We quote prices at present as follows: Fancy white comb honey, 1-lb. paper cartons, 14@15c; same glassed or unglassed, 13@14c. 2-lb. cartons, glassed, 10½@12c; same unglassed, 12@13c. Fancy buckwheat comb honey, 1-lb. paper cartons, 11@12c; same in 2-pound paper cartons, 9@10c. Extracted, white clover, 6½@8c; buckwheat, 5½@6½.

McCAUL & HILDRETH BROS.,
Dec. 22, 1885. 34 Hudson St., New York, N. Y.

NEW YORK.—*Honey.*—There is still a good demand for all grades of comb honey. Receipts are few and small, as the bulk of honey has been sent to market. We quote: Fancy white, 1-lb. sections, 14@15c; 2-lb. sections, 11@13c. Off grades, 1-lb. sections, 12@13c; 2-lb. sections, 10@11. Buckwheat, 1-lb. sections, 11@12c; 2-lb. sections, 10@11. Extracted, white, 6½@7½; buckwheat, 5½@6c.

THURBER, WHYLAND & CO.,
Dec. 21, 1885. Reade & Hudson Sts., New York.

CHICAGO.—*Honey.*—Our stock of best grade of white comb honey is low; and now that a thaw is promised by the weather-prophets, it would be a good time to ship honey. One-pound sections bring 16c; 1¼ to 1½ to 2 lbs., 13@15. Extracted is also in demand at from 6@8c, according to quality and color. *Beeswax,* 25@26c. R. A. BURNETT,
Dec. 21, 1885. 161 S. Water St., Chicago, Ill.

CINCINNATI.—*Honey.*—There is no change in prices since our last. The stock seems to accumulate on the market, while demand is exceedingly slow. *Beeswax.*—There is a fair demand for beeswax, with no change in prices.

Dec. 22, 1885. CHAS. F. MUTH,
S. E. Cor. Freeman and Central Avenues,
Cincinnati, Ohio.

ST. LOUIS.—*Honey.*—Our honey market is quiet. Southern, in barrels, 5@5½c. Northern, in kegs, about 7c. Comb honey, white-clover, 15@16. Fancy worth more. Dark honey hard to sell — normal. *Beeswax,* 22½@23 for choice.

Dec. 23, 1885. W. T. ANDERSON & CO.,
104 N. 3d Street, St. Louis, Mo.

BOSTON.—*Honey.*—Best 1-pound sections, 14@16; best 2-pound sections, 12@14. Slow sale. No demand for extracted. BLAKE & RIPLEY,
Dec. 21, 1885. 57 Chatham St., Boston, Mass.

SECTIONS.

Western headquarters for bee-men's supplies. Four-piece sections, and hives of every kind, a specialty. Flory's corner-clamps, etc. Orders for sections and clamps filled in a few hours' notice. Send for sample and prices.

M. R. MADARY,
22 21db **Box 172. Fresno City, Cal.**

WE WILL SELL

Chaff hives complete, with lower frames, for $2.50; in flat, $1.50. A liberal discount by the quantity. Simplicity hives, Section Boxes, Comb Fdn., and other Supplies, at a great reduction. We have new machinery, and an enlarged shop. **Italian Bees and Queens.** Send for Price List. 23 22db

A. F. STAUFFER & CO., Sterling, Ills.

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY & HOME INTERESTS.

Vol. XIV. JAN. 1, 1886. No. 1.

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent to ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

NOTES FROM THE BANNER APIARY.

NO. 73.

OR, TO BE MORE EXACT ABOUT THE FACT, NOTES FROM THE DETROIT CONVENTION.

SECTIONS.

IN the east, glassed sections sell better than unglassed; but Western people object to paying 15 cts. a pound for useless glass. The market demands sections of different sizes; but the one-pound leads the van. Spruce and poplar should be substituted for basswood, as they are harder, and it "saves the basswood."

FOUNDATION VS. EMPTY FRAMES.

Have small brood-nests, put only starters in the brood-frames when you hive a swarm. Try it, ye doubters.

EXTRACTED HONEY LOSES ITS FLAVOR

by being exposed to the air.

KEEPING COMB HONEY.

Comb honey can be kept by having it in a dry warm atmosphere. Have no pollen in it, and the moth will not trouble it. The fumes of burning sulphur settle. Have the honey at the bottom of the room. Set fire to the sulphur by throwing into it a hot iron.

50 LBS. OF SUGAR SYRUP.

Two parts sugar and one water, fed to a colony of bees in the fall, will enable them to build combs in empty frames, store the syrup, and winter well in a cellar.

ALSIKE CLOVER

can be grown at a profit, as a honey-plant, on land worth $50 per acre. It has yielded more than $25 worth of seed per acre. Sow the seed of honey-producing plants, those that produce honey alone, upon waste places *only*.

BEES BY THE POUND

should not be gorged with honey, and, when shipped, should be furnished with "Good" candy, and kept out of the sun. To secure good results, the bees should be young and the apiarist skillful.

BEE-STINGS, GLOVES, CLOTHING.

Cut off the ends of the fingers of rubber gloves; it allows the sweat to escape. They are then more comfortable, and last longer. Wear smooth clothing, singe the hairs from the hands and wrists, and the number of stings received will be lessened.

COMB FOUNDATION.

If the wax is the same, the "make" of fdn. has but little to do with its acceptance by the bees. Comb drawn from fdn. is tougher than natural comb, hence the fdn. in surplus honey should be *very* thin. Roller-mills can make thin fdn. if the wax is *not* sheeted thin; presses can not. Fdn. that has been closely boxed is hardened but little by age. Soaking old fdn. in warm water will remove the bluish color that it has acquired, and make it soft.

BEE-KEEPING AS A BUSINESS.

Whether bee-keeping "pays" as compared with other business, depends upon the "other" business. If one can make more at some other business, then it doesn't "pay;" if not, then it does. Each one must take *every thing* into consideration, and decide for himself.

REVERSING COMBS.

Besides the oft-repeated advantages of reversing combs, there is now claimed the additional one of its discouraging swarming by enlarging the brood capacity of the hive, and sending the honey into the surplus apartment. If inverted at the right time, queen-cells will be destroyed. Mr. Heddon has invented a reversible hive and section-case.

WINTERING BEES IN CELLARS.

The temperature of our bee-cellars can be kept higher than we have generally supposed. From 60° to 90° have given excellent results. With a high temperature, no absorbents are needed. A damp cellar requires a higher temperature than a dry cellar. But little ventilation is needed. Bee-bread in the hives does no harm, if the conditions are such that the bees do not eat it; and it appears that a high temperature is one of the conditions. In a warm cellar, bees will breed in the latter part of the winter, and weak colonies thus become strong. Prof. Cook explained that bees could breed without taking pollen into their intestines; but Wm. F. Clarke asserted (and was supported by Bro. Jones), that the rearing of young was the *hardest kind of work*, requiring the consumption of nitrogenous food by the *bees themselves.*

DIFFERENT RACES OF BEES.

Pure Syrians and Cyprians are excellent bees for warm countries, but not for Canada. When pure races meet the requirements it is well to have them in all their purity. Crosses between Italians and Cyprians or Syrians, and between Carniolans and Cyprians or Syrians, give the best result. The blacks are excellent comb-builders, and keep the honey out of the brood-nest.

TAKE PAINS IN REARING DRONES,

the same as in rearing queens. Remember that prepotency is on the male side.

PUT THE BROOD-COMBS CLOSE TOGETHER,

and it will "squeeze" the bees into the sections. The combs can be close together as 1¼ inches from center to center. This also discourages the building of drone-comb.

"ACCORDING TO NATURE."

This phrase has been a stumbling-block in the way of advancement. It is not a question of "naturalness," but it is, "all things considered, is it best?"

If I have not, in the above brief notes, given the proper expression of the convention, I hope to be corrected. W. Z. HUTCHINSON, SEC.

Rogersville, Mich.

Friend H., you have given the sum and substance of the principal points discussed while I was present at the convention, and we owe you a vote of thanks for having succeeded in boiling it down so well, only you have got it a little *too* brief, if any thing. I would remind our friends that the conclusions arrived at which you have, I believe, truthfully reported, were, at least many of them, decided upon only by prolonged and exhaustive discussion; and the intelligence that was brought to bear on these subjects, and such keen, strong intellects that grasped the different points, are not often brought together in one meeting. I was not present when the point you mention, "According to Nature," was discussed; but I have often felt what you express there. We do not manage bees according to nature, nor strawberries, nor anything else, nowadays; but we make even the frost and the snow, the thunderbolt and the torrents, do our bidding; and who shall say that we may not some time, after a feeble fashion, perhaps, make the winds and the waves obey us, something in the way they obeyed the Master in olden time?

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

ARTIFICIAL EGGS AS WELL AS ARTIFICIAL COMB HONEY.

INCLOSED I send you a slip cut from the New-York *Tribune* of Dec. 15th, in regard to artificial eggs. As things artificial are being much discussed, and as some claim that a poultry-yard is a necessary auxiliary to an apiary, I inclose the above, hoping that, if you find it interesting, I shall hear your views in regard to it in GLEANINGS.

Yonkers, N. Y., Dec. 16, 1885. G. WIEDERHOLD.

Friend W., I am very much obliged to you for the slip inclosed. Since you sent it, it has been copied widely into other papers. I will make a few extracts for the benefit of our readers:

In the back room of a Broadway office a curious invention was exhibited yesterday to several provision dealers and merchants. The invention consisted of a number of artificial eggs, which resembled the real article so exactly that none but an expert could distinguish them. The shells were made of a clear, transparent composition, and the shape was perfectly modeled. The portion surrounding the yolk was made of albumen, and the yolk itself of ground carrot and saffron. Three of these artificial eggs were placed on a platter by the exhibitor with half a dozen real ones, and the men present were told to select the bogus ones from the collection. The first expert exposed his ignorance by picking out three real eggs and declaring them to be artificial. The second, with a little better luck, owing partly to his avoiding the three selected by his unfortunate predecessor, managed to pick out two of the real eggs and one of the artificial ones. Thus with varying results each of the six men tried his skill in determining the difference between the eggs by their appearance. When each had had a trial, and failed, the exhibitor said:

"Now, gentlemen, you can test them in another way." A frying-pan was then placed on the stove, and in a few minutes it began to simmer. Two of the artificial eggs were picked up, their shells broken, and the contents dropped into the hot pan where they soon began to simmer and sputter. A little salt and pepper, a brisk two minutes' stirring with a fork, and as fine a dish of scrambled eggs as could be prepared at a restaurant was placed before the expectant guests.

"Help yourselves, gentlemen. They are as good as the real article. Nothing poisonous or disagreeable about them."

This invitation was complied with at once, and the several verdicts were: "Delicious," "Better than the real article," "What are they made of?" "They are not artificial, but fresh eggs from the country."

"Well, gentlemen," smilingly responded the exhibitor, "whether real or artificial, I can make any quantity of those eggs at a cost of about half a cent apiece, while you can not buy their equal for less than two or three cents. You have just had proof that you can not tell them from the real article by their appearance or by their taste when scrambled. In an omelette there is equally no perceptible difference, but when boiled the imposition is much more easily detected. But even then nine people out of ten would be deceived, as the only difference lies in the fact that the yolk and surrounding white portion will not harden separately as they do in the real egg. The flavor is about the same, which after all should be the main consideration. It is my intention to put these artificial eggs on the market soon, and my object in inviting you here to-day was to make you favorably impressed with them. I think I have done it. Good-day, gentlemen."

Of course, the above is a newspaper canard, and nothing else; but I do think the N. Y. *Tribune* might draw a little stronger line between truth and fiction. As if to mislead such of their readers as might not readily comprehend the above sell and joke, they go on in the same article as follows:

> There is some stir in Paterson over a theory entertained by some provision-dealers that somebody has been imposing on them with artificial eggs. Garrett Onderdonk, a farmer from Rockland County, N. Y., came into Paterson on Saturday with a lot of eggs which he sold to various dealers. George W. Saunders, a grocer, bought some, and found, as he alleges, that they were not genuine, as they had been represented to be. Saunders went before the Recorder and made a complaint against Onderdonk, alleging that the eggs were sold as fresh country eggs, whereas they were what are known in the trade as "pickled eggs," and that thereby a law of the State of New Jersey against the sale of adulterated food products was violated, the eggs having been treated by some peculiar process so as to look like a recent barnyard product. Onderdonk was arrested and pleaded guilty, and Recorder Greaves fined him $50, which Onderdonk paid and left the city. He has not returned since.

But, what has this transaction to do with artificial eggs? Why, nothing at all, of course; but the Cleveland *Leader* of Dec. 16 lays hold of it, and then announces:

> In our telegraphic columns will be found an account of the arrest and punishment of a man who pretended to be a Rockland Co., N. Y., granger, and sold to Paterson, N. J., merchants several dozen bogus eggs. The shells were made of a transparent composition, and were perfect in shape; the whites of albumen, and the yolks of ground carrots and saffron. In boiling, the bogus character of the eggs was easily seen, but it is evident that the imitation was a very good one.

This is a fair illustration of the way in which unscrupulous editors pass about these fraudulent statements. I am glad they have got to telling such abominable falsehoods that any one of good common sense knows better. At our teachers' meeting a few nights ago our minister made the remark, that when people commence telling falsehoods about us if we let them alone they will soon overstep the mark so far that no one will believe them, thereby killing what influence they possessed themselves; or, if you choose, branding themselves as liars, without any necessity for the innocent party to say a word. It seems as if it were going to turn out so in this case. And now I have been wondering if it were not about time for bee-keepers to write to editors who have been publishing these statements, and give them to understand that we as a body of bee-keepers propose to refuse to subscribe to any paper that gives place to these slanderous statements. If they have been giving place to them innocently or by falsehood, is it going too far to demand that they recall or contradict the slanders cast upon us? I hardly need say, that it is beyond the power of man to make any thing that could be called even a tolerable *imitation* of an egg. The stories in regard to it now going through the press are a disgrace to an enlightened nation. One editor, as if to shame his cotemporaries, has already announced that these artificial eggs are not as yet *quite* capable of being hatched into chickens, but that the inventor thinks he will fetch *even that* in a *few days!*

LATER.—The following is sent us by one of our subscribers, who clipped it from the Cincinnati *Commercial:*

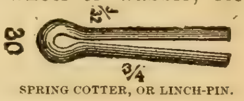
> ARTIFICIAL EGGS.
>
> NEW YORK, Dec. 15.—A number of dealers in eggs and produce in Paterson were called on, Saturday last, by a man representing himself as Garrett Onderdonk, of Rockland Co., N. Y. He sold each a load of fresh country eggs at a remarkably low figure. The eggs were delivered by another man, to whom the dealers refused payment. Yesterday Onderdonk called for his money, but was arrested, under an act prohibiting the sale of adulterated food. He pleaded guilty, whereupon he was fined $50.00 and costs. This he paid promptly, and left the city without attempting to collect for the eggs delivered. He admitted to several dealers that the eggs were artificial, and were manufactured by a firm in Newark, whose name he declined to disclose. The shells were made of a clear, transparent composition, and the shape was perfectly modeled. The portion surrounding the yolk was made of albumen, and the yolk itself of ground carrot and saffron.

Onderdonk was simply arrested and fined for selling stale eggs; the *Leader* changes it to "several dozen" *artificial* eggs, and the *Commercial* jumps to a "load" to *each* of a "*number of dealers.*"

SPRING COTTERS AND GIMLET-POINTED HOOKS.

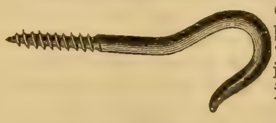
SOME USEFUL HOUSEHOLD ARTICLES.

WHO has not felt the need of a better "linch-pin," not only for children's carts, wagons, and carriages, but for different kinds of agricultural machinery? A bent wire is often used, but it is not strong, and gets twisted, and drops out, and then something must be procured as a substitute. A nail is driven, and this either drops out again, or splits the axle. If you try to bend it over it breaks off, and is unsatisfactory any way. A wire nail does better, for it can be bent so as to prevent dropping out; but this same bending property makes it bend when you don't want it to, allowing the wheel to wabble, etc. The cut adjoining shows what is called a spring cotter. It is made of tempered steel wire, shuts up easily with the fingers when you wish to put it into the hole, but springs open again so it can neither rattle nor drop out. I found them in the price list of a wire-goods circular, and we have procured and now keep in stock 10 different sizes, length as follows: 1 inch, 1¼ inch light, 1¼ inch heavy, 1½ in. light, 1½ inch heavy, 1¾ inch light, 2¼ inch heavy, 2½ inch light, 2½ inch heavy, and 3 inch heavy. The first 6 are sold at 10 for 5 cts.; the next 3 are sold at 5 for 5 cts., and the largest size at 3 cts. each. This last is just right to fill a ½-inch hole.



SPRING COTTER, OR LINCH-PIN.

Besides the above, we find, in the same catalogue, gimlet-pointed wire hooks which we illustrate in the cut adjoining. We keep all of these in stock, 4 sizes — 1½ inches long, 2 inches, 3½ inches, and 4½. The first two are 10 for 5 cts.; the next largest, 5 for 5 cts.; largest size, 3 cents each. The largest size would probably hold 500 lbs.; the smallest size, perhaps 10 lbs. If these goods are wanted by mail, add one-fourth the amount for postage.



GIMLET-POINTED HOOK.

EIGHT OR TEN FRAMES, WHICH?

GOOD REASONS FOR PREFERRING THE LATTER; CONTRACTING.

BEFORE this question drops out of discussion I wish to say a few words on the subject. For the two last seasons I have been testing hives of eight-frame capacity. My experience is not extensive with such small brood-apartments, but sufficient to furnish a pointer in the right direction. Since quite a small boy I have kept an apiary of an average of 75 colonies. I am now 43 years old. This gives me, as you see, a deal of experience, especially when I tell you that I have used hives holding all the way from one peck to five bushels, and have used frames of nearly all shapes and sizes.

About twelve years ago I settled down to the use of a hive containing ten L. frames, which seems to me to be the nearest the proper size of any other for most localities. By the use of contractors, suitable space may quickly be arranged to suit the requirements of any size of colony; and by the use of chaff division-boards, or contractors, made to take the place of the two outer frames, the space is reduced to the capacity of an eight-frame hive, and that, too, without interfering with the size of the surplus apartment. Cases and crates used for ten-frame hives in the surplus apartment may also be used on the so-arranged eight-frame hives, and no confusion. So much argument was produced in favor of eight-frame hives, I decided to reduce the brood-apartment of a dozen hives to this number, which was done by the before-described method.

During the first season's experience with these hives, my bees were at no time, by a good honey-flow, led up to the swarming-point.

About the same amount of surplus was taken from these eight-frame hives that was taken from my ten-frame hives. By a close estimate the small hives contained 9 lbs. less honey to begin the winter on than the ten-frame hives had; and as no honey was gathered the following season before June 10th I had to draw on the ten-frame hives for honey to run the small hives through.

Here it may be well to remark, that as it is true that farmers and nearly all bee-keepers having less or more bees, but making this branch of rural economy but a secondary matter, will be found negligent in the care of their bees, and, in consequence, would lose more extensively with hives of small capacity. Hence it may be easily seen that even the specialist must give more time, more labor, and more frequent manipulations where small hives are used.

As my second season's experience with the eight-frame hives was even worse than the first, I soon abandoned the use of them. Soon after the honey-flow began, and just as my bees had made a fine start in the sections, the swarming fever broke out in the apiary, and within three days 11 of the 12 eight-frame hives had swarmed, while but one in six of the ten-frame hives swarmed that season; and as I wished to conduct my apiary as far as possible on the non-swarming principle, I at once was out of conceit of hives of less capacity than ten frames. There is a difference of opinion about this matter of running bees on the as-far-as-possible-non-swarming plan; but with me this plan is the most profitable, and reduces the running expenses, as well as the labor of the apiary, to the minimum.

If I may be indulged further I should be pleased to say a few words on the question of

CONTRACTION.

Taking into consideration the extra time and labor of, first, contracting the brood-nest to five or six combs, at the time of putting on sections, trouble in disposing of the extra combs removed, the materially lessened room left *immediately above* brood-combs for sections; and, second, the returning to place combs that were taken away, cost of sugar, preparation and feeding of same, expense of feeders, etc., would the apiarist be any better off with this system of management than he would be were all the frames left undisturbed in the brood-apartment throughout the year, and take what surplus the bees were able to produce? I am of the opinion, that, taking a number of years in succession, the best results would be obtained by leaving all the frames in their proper place. What can be gained by forcing all the honey into the surplus receptacles, to be extracted and sold in a hard market at 7 cents per lb., "keg thrown in," then go home, buy sugar at about the same price to feed up again for winter? Yes, I've tried this too. Why not take just what your bees can spare, stored in sections, or surplus combs for the extractor, and, when removed, replace your slatted honey-board, put on quilt, then chaff cushion, and go away from them? They are ready for the winter. J. A. BUCHANAN.

Holliday's Cove, W. Va., Dec. 10, 1885.

Friend B., although I have not experimented as you have, I had come to the same conclusion you do, and for about the same reasons. The greatest reason besides the above is, that the eight-frame and ten-frame hives could not be made interchangeable when used on the Simplicity plan. I think it would be a serious mistake to commence making narrow hives.

THE HONEY-MARKET OF NEW YORK.

SINGLE-TIERED CRATES VERSUS THE DOUBLE-TIERED; ADULTERATION OF FOOD.

DURING my stay in New York I have taken some pains to look into the honey-trade of that city, and the results of my investigations are as follows. Thurber, Whyland & Co., have on hand from 50 to 60 tons of as fine a lot of honey as I have seen. Messrs. McCaul & Hildreth Bros., who give quotations of honey in GLEANINGS, have about 35 tons. Something over half of these lots of honey is comb honey, put up in single-tiered crates; that is, those having but one layer of sections. These crates are very similar to the Heddon-Hutchinson style — a cut of which appeared in the last issue, and do not hold over 15 or 20 lbs. of honey. Neither of these firms cares to handle honey in the double-tiered crates. The reasons given by them for rejecting the double-tiered crates are about as follows, and are similar to those given by Heddon:

The sections are not as easily gotten out, are more apt to be daubed, and during shipment are not as liable to be broken. I am satisfied, from conversation with these gentlemen, that the 48 or 50 lb. crate or case is undesirable, being both unwieldy by reason of its weight, and not as salable as the smaller package. It is no easy task to lift a 50-lb. crate of honey to or from a wagon or car. A smaller crate will always insure more careful handling, and therefore be less liable to breakage. Again, consumers prefer to buy the smaller packages to the larger. These reasons have already been considered before, but are the opinions of the large wholesalers. Although honey is selling well at present, these wholesalers state that it is difficult to conceive the amount of damage and pernicious effect these newspaper canards have had upon the trade. They can scarcely convince their customers that their honey is the pure article, such has been the effect of these sensational falsehoods on the market of New York.

THE ADULTERATION OF EGGS AND HONEY.

Now that the papers have proven to *their* entire satisfaction that comb honey can be successfully manufactured, they come out, with unblushing ignorance, with a sensation more ridiculous; namely, the manufacture of eggs, a clipping of which I sent, and appears in another column. You observe, that they *assume* that comb honey has been manufactured, and that "Yankee ingenuity" (of which we ought to feel so proud) has made another big stride (?) in manufacturing the egg. They even claim that not only the yolk and the white of the egg have been imitated, but assert that the film just outside, and adhering to the shell, has been made. Then with apparent candor that savors of the false statements of the honey trade, state that these eggs can not be detected from the genuine, except as they are boiled. In conversation with a number of prominent New York merchants dealing in dairy products, I learned, as I had expected, that the thing was a falsehood, and an utter impossibility. Below will be found a clipping that is just to the point — taken from Harper's *Weekly*, page 859:

> Of all things that are ridiculous one would least like to believe that an artificial egg can be made so nearly resembling a hen's egg that a man will break it, and put salt on it, and eat it with a spoon, without suspecting that it was not laid by a hen. Such eggs, however, have been exhibited in this city, according to (false) report, and it is declared that they can be made and sold at a profit for half a cent apiece. It beats all; nothing is impossible if this is true. Will it, however, be too much to ask the inventor, after the world has become convinced of the reality of the perfect imitation, to make a new and more convenient style of shell for the eggs intended for common use? The shells should be a trifle tougher, if it is not impertinent to say so, and should be made to unscrew, and be provided with some sort of little antiphlogistic handles, so that one may open them, when boiled, neatly and without pain.

Now, if the same inventors referred to in the above will turn their miraculous genius (?) to manufacturing an article of comb honey whose cells will be like india-rubber, will not melt down, break, smash, or leak, and yet retain the appearance of comb honey, they will confer an everlasting boon on humanity. We shall then have eggs that "unscrew," honey that won't smash. If said papers continue at this astounding rate, "Yankee ingenuity" will produce artificial fish, oysters, lobsters, and what not at a very small cost. I do not mean to condemn *all* newspapers. They have their legitimate place, and are almost indispensable to the public; but when they meddle with business that they know nothing of, I think it is time to protest. No doubt milk and butter have been adulterated to some extent, and it is proper that such frauds should be shown up; but it is not a fair conclusion to infer that all other foods are adulterated as well. **Ernest R. Root.**

Passaic, N. J., Dec. 24, 1885.

BEES EATING CLAY.

ALSO SOME KIND WORDS FROM AN OLD FRIEND, FOR GLEANINGS AND HIS BROTHER BEE-KEEPERS.

IT is now nearly half a century since I commenced to handle bees. I have been engaged in bee culture ever since, and found it profitable, and very interesting, and pleasant. My apiary is nicely located near the public highway, most of it shaded with grapevines. My hives combine mostly the modern improvements of the age.

Within a few rods of our apiary we have a beautiful vineyard, and keep many sheep, all on the same farm, where white clover is abundant; yet I have never discovered that any one of them has been a serious injury or detriment to the other. If any distinction can be made, I should think it would be in favor of the bees. As it has been quite cold, and the ground frozen for some time, the bees could not venture out. But as it has now thawed, and teams have cut up the fresh yellow clay, while the bright sun and wind are drying this clay it reminds one of fresh maple sugar just stirred off.

Well, on the 24th the air was so balmy, the sun shining bright, my bees concluded that now is the appointed time to get a good dinner from the soft fresh clay, preparatory to another cold blast—guided, no doubt, by the same instinct and desire that directs large animals, such as horses, hogs, sheep, and other clay-eating animals.

Now, let me tell you how I was delighted with the bees yesterday. While I was helping one of my sons, who are farmers, to put a new bottom in a wagon-box (as I am a wood mechanic), and working on the opposite side of the public highway near the apiary, we were busily at work when I heard a sound of bees, much like that of swarming. We stopped work to discover what they were up to; the air appeared to be filled with bees, flying thick as in June. They were flying in various directions, and alighting on the ground. I soon discovered what they were up to, so I laid down my tools to watch them, as I have often done at other times. The road was dotted thick with bees, as I could distinctly see when looking toward the sun. I observed them in many other places where the clay had been lately disturbed. I do not think they were seeking water, as it was plentiful and not difficult to get. After closely watching them they invariably seemed to select the dryest clods, and, as nearly as I could ascertain, they appeared to me to be eating clay. If so, perhaps the want of it is the cause of diseases which the long cold weather is very likely to bring. Well, the result was, the wagon-box did not get finished that day, as such a fine opportunity offered to go about watching these little creatures, to find just what they were really doing.

It is a rare thing to see bees out in such force, and at this season of the year up here near the northern lakes, and so deeply and busily engaged on the ground as to take little or no notice of any thing else, although when I would put my glass too near their little nose in order to find out what they were really doing, by my prying into their business matters too much they would become indignant at my impertinence, and reluctantly fly away in such a manner that I almost fancied I could see them lay their little ears back with "pure mad."

Well, just at this time a bundle of mail matter came, so I went to the house and opened the package, when out tumbled GLEANINGS. On the wrapper the word, in large capitals, "NOTICE." Then followed, in smaller type, these words: "If we are correct, your subscription expires with the present month." (Just like Mr. Root; he did not want to be too positive, although he felt quite sure.) Oh, if all men would be as careful, what a world of pleasure this would be! Then on the wrapper I further read: "If you have found GLEANINGS so far a good investment, we shall be pleased to continue your name on our list. As this is a question that rests with you alone to decide, we can only tender you our thanks for past patronage, and wish you success in bee culture for the future, whether your decision should favor ours or not."

Now, how was I to decide such a case as that? In my library and on my table is a copy of nearly all the bee-journals published. I can not well afford to take all of them, nor would it be good economy to do so. Well, friend Root, I have not a word of disparagement to say of any of these bee-journals; but I find, as GLEANINGS has been coming regularly for years, not one copy was missing or out of regular time. It has more than filled my expectations, and proved of great value and satisfaction to me. I consider it a very good investment, even if I keep no bees. As to its arrangement as a bee-journal, I would not attempt to dictate, nor could I make any suggestions that would be an improvement; so, as my name is on your list, I will send you in this mail an order for another year's subscription.

Remembering you for your kindness and fair dealings, with the many good things I have read in the A B C and GLEANINGS, permit me to thank you, wishing you a happy Christmas and prosperous new year; extending the same to all the bee-friends, and especially those who have contributed so many good things to me through GLEANINGS, I am, respectfully, JOHN W. NIMAN.

Spring Mills, Ohio.

Thank you, friend N., for your very kind letter; but it seems to me your experiment is hardly conclusive, that the bees really gathered the clay and not the water it contained, unless you saw them pack the yellow clay, like pollen, into their pollen-baskets. We have had reports of bees packing black peaty soil, just as they pack pollen, and carry it into their hives, and I should not think it very strange if they sometimes used some kinds of yellow earth. It is well known, the way in which they appropriate sawdust; and why may not this material answer as well? Can any other friend give us any light on the subject? and do they pack clay on their legs?

NOTES AND QUERIES.

A REPORT FROM MRS. L. HARRISON.

THE winter thus far in this locality has been very favorable for bees on their summer stands. I notice that, from hives protected most, fewest dead bees are carried out. Bees flew finely several days this week; and after they were quiet, part of them were stored in the cellar. The dozen queens purchased of you last summer all proved satisfactory.

Peoria, Ill., Dec. 26, 1885. MRS. L. HARRISON.

TEMPERATURE OF THE EARTH AND WELLS.

I have just tested the water in my well, which is 25 ft. deep. The temperature is 45°, water pumped from the bottom. Temperature of the atmosphere, 24 above zero at the time of test. I made a test during the warm weather of summer, and the temperature was no higher than now.

H. R. BOARDMAN.

East Townsend, Ohio, Dec. 26, 1885.

TEMPERATURE OF DEEP WELLS.

I have just read friend Doolittle's remarks, and your comments, on "Temperature of the Earth," and tested my 60-foot well with two good thermometers by completely immersing them in a freshly drawn bucket of water. The bath showed exactly 54 degrees. Terre Haute lies between 39th and 40th degree north latitude. T. H. KLOER.

Terre Haute, Ind., Dec. 25, 1885.

HONEY-PAILS; WIRE CLOTH AS A FRUIT-TREE PROTECTOR.

I was well pleased with my honey-pails, and find it the best way to handle extracted honey. I think my experiment with the wire cloth as a fruit-tree protector is going to be a success. If so, look out for orders for wire cloth from this locality next season. I will send my honey report for this year soon. W. G. CONDON.

Clinton, Mo., Nov. 10, 1885.

FROM 300 STANDS TO 500; 8925 LBS. OF HONEY, $150 IN CASH, AND 500 LBS. OF BEESWAX.

Bees are in good condition. I commenced in the spring with 300 stands of bees; sold 50 stands at $3 a stand; increased the remainder to over 500 colonies, all in good condition; also got 15 barrels of honey, each barrel holding 45 gallons, and got 1500 pounds of comb honey in sections; also by pruning and cutting out all drone-comb I have accumulated 500 pounds of beeswax, which I think is not a very bad crop for this year's work. E. STAHL, JR.

Kenner, La., Dec. 28, 1885.

SCREENS FOR FISH; SWINDLES.

Yours with zinc, received. If thicker, this material would answer for small screens, temporarily. There would be danger of breaking them when cleaning. Heavy, substantial galvanized-wire screens are safest, and consequently best and cheapest.—Look out for the newspaper swindler "Bain," with his pretended "Fish-Cultural book," alias LeMorris, alias U. S. Fish Co., Columbus, Ohio.

MILTON P. PEIRCE.

Philadelphia, Pa., Nov. 24, 1885.

[The above refers to the Jones perforated zinc which I sent friend Peirce, with inquiry if it would not answer for outlets to carp-ponds.]

A WOMAN'S SUCCESS.

Mrs. Thomas, of Philadelphia, reported at a meeting of bee-keepers in Trenton last month that she had obtained an average of 150 lbs. of honey from 20 colonies, or a total crop of 3000 lbs. This was extracted honey, for which she received 25 cts. per lb., netting her, therefore, $37.50 per hive. She also cleared last year $1000 from her poultry-yard, and runs a twenty-acre farm besides.

[The above was clipped from one of the newspapers. The price our friend received for her honey, it seems to us, was extravagant; but the yield mentioned is not extraordinary. Perhaps we should make some allowance for newspaper exaggeration, but I am rejoiced to know that women can manage these rural industries with as much wisdom, and many times more, than our own sex.]

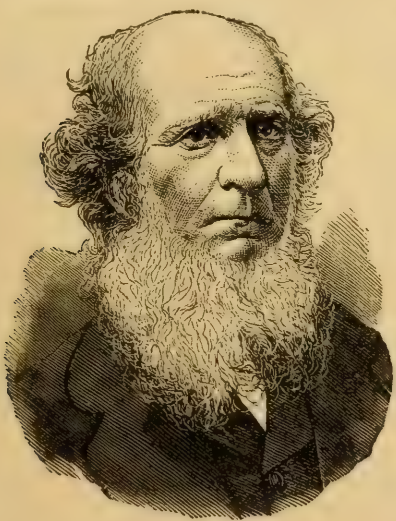
IN MEMORIAM—WM. W. CARY.

FROM OUR OLD FRIEND MR. LANGSTROTH.

HE was born in Coleraine, Mass., Feb. 24, 1815, and died Dec. 9, 1884.

It affords me a melancholy satisfaction to review my long acquaintance with the late Mr. Wm. W. Cary, and to set out more fully than has yet been attempted, some of the important services which he rendered to bee-keeping. To do this seems to me the more obligatory, as he so seldom used his pen for the press that these services might fail to be put on record.

After testing quite largely my movable-comb frames in West Philadelphia, in the bee-season of 1852, in the fall of that year I went to Greenfield, Mass., to introduce my hive were I was best known as a bee-keeper. Mr. Cary kept some bees in the adjoining town of Coleraine, and was among the first to take an interest in my invention. He was very fond of bees, and more than usually familiar with their habits—and as soon as he saw the working of the hive, he believed that it would make a revolution in bee-keeping. For the six years that I remained in Greenfield, we were in such frequent communication that, in furthering my experiments, his apiary was almost as much at my service as my own.



WILLIAM W. CARY.

In the spring of 1860 I was invited by Mr. S. B. Parsons, of Flushing, L. I., to advise him how best to breed and disseminate the Italian (Ligurian) bees which he had recently imported. Finding that the person who came in charge of most of these bees could not do the work that was expected of him, I advised Mr. Parsons to secure the services of Mr. Cary. To great energy of character, and good business habits, he united long experience in the management of movable-frame hives, with an enthusiastic desire to see the introduction of these foreign bees made a success. From my intimate acquaintance with him I could further assure Mr. Parsons that, with all these requisites for the position, he possessed in as large a degree as any one I had ever known, that "highest fidelity" which Columella, nearly 2000 years ago, declared to be an essential qualification for the superintendence of an apiary—and which he thought was very rarely to be met with. Is it much easier to find that now than it was then?

Mr. Cary's work in Mr. Parsons' apiary fully justified his selection. While the foreigner, in a separate apiary established by Mr. Parsons, and furnished with just the same facilities for breeding queens, failed to rear enough even to pay for the black bees and feed he used in his operations, Mr. Cary supplied all the queens needed in Mr. Parsons' apiary, and filled all his numerous orders.

No better proof could possibly be given of the extent and thoroughness of his work, than the fact that 113 queens bred by him that season were so carefully prepared for shipment, under the joint supervision of himself and Mr. A. G. Biglow, that all except two of them were safely carried by Mr. Biglow from New York to San Francisco! Mr. B. had stopped over one steamer on the Isthmus of Panama to give his bees a cleansing flight, and one queen entering the nucleus of another, both were killed. The colonies to which they belonged, when examined on their arrival at California, were each found to have reared another queen.

To appreciate fully the extraordinary success of Mr. Cary as a breeder and shipper of Italian queens, it needs but to be stated that during this very year but few queens came alive, out of the many sent from Europe, and that, for years after, a large part of our imported queens either died on the way, or arrived in such poor condition as to be of little or no value. It will be remembered by some of the old readers of the *American Bee Journal*, that Mr. Cary was the first person to send a queen across the ocean, in a single-comb nucleus, with a few workers. She was consigned to my lamented friend, Mr. Woodbury, of Exeter, England, and reached him in excellent condition. Those who now receive the queens which are sent by mail from Europe, and even from Syria, should bear in mind that only after many and costly experiments has such admirable success been secured.

After his splendid achievements in Mr. Parsons' service, Mr. Cary greatly enlarged his own apiary, and placed himself in the front rank of reliable breeders of Italian queens.

When Dr. E. Parmly, of New York, imported a number of Egyptian queens, he entrusted them to Mr. Cary, having, as I know, as strong confidence as myself in his sagacity and fidelity. Mr. Cary first called my attention, in his own apiary, to the inferior appearance of the comb honey of those bees. It was capped in such a way as to look like honey damaged by "sweating"— so called — after being kept in too damp a place. He was also the first to notice that Egyptian bees, in extending their combs, built their lower edges almost perfectly square throughout their whole length — in marked contrast to the way in which black bees build them — and improving in this respect even upon the Italians. Although I imported the first Egyptian queen, Mr. Cary had the largest experience with this variety, and after a fair trial we both discarded them as very much inferior to the Italians.

While Mr. Cary was a great enthusiast in bee culture, and always ready to accept every discovery and improvement, he was not carried away by plausible novelties or conceits. When near him, I always took peculiar pleasure in communicating to him all matters that from time to time were engaging my attention, and our occasional meetings in later years were highly prized. He seldom failed to detect any flaw in what was submitted to his judgment, and his deliberate "yes" or "no" had greater weight with me in bee-matters than that of almost any other person.

Mr. Cary's location was inferior in honey-resources to those who in this country have achieved the greatest pecuniary success from the keeping of bees; he was also quite lame, from an accident in his youth; yet notwithstanding these and other obstacles, he built up gradually a large apiary. He was not only a strictly honest man, but a highly honorable one in all his dealings; and in cases of doubt he made it his rule to give his customers the benefit of that doubt, instead of claiming it for himself. Like myself he had the help of an only son in the management of his business; but, happier in this respect than myself, he was not called to lament his premature death.

Mr. Cary's interest in bees ceased only with his life. A few weeks before his death he was able to be out in his apiary, where he witnessed with much pleasure some novel arrangements for the safe wintering of a colony in the open air.

Samuel Wagner, Moses Quinby, Richard Colvin, Adam Grimm, Roswell C. Otis, Wm. W. Cary — they have all passed away! And probably no one knows better or appreciates more highly than their old friend who still survives to honor their memories, how much their various labors contributed to the splendid success of the movable-frame principle in American bee-keeping. L. L. LANGSTROTH.

Oxford, O., Nov. 10, 1885.

Perhaps we should apologize to our readers for giving the above so long after it has appeared in other journals, especially as the main part of GLEANINGS is, as a rule, original matter. In sending to us the copy, friend L. requested that it should not be put in print until the engraving of friend Cary was sent us, and it has only just come to hand.

REMOVING THE FRAMES FROM THE UPPER STORY OF CHAFF HIVES.

AN ADVERSE REPORT FROM SOUTHERN OHIO.

FOR some years past I have been a silent but appreciative reader of your journal, and have gained many valuable hints from its pages. It is always up to the times in advocating the use of new implements that are of real value to bee-keepers, and its columns are always open to suggestions as to any alterations of implements, hives, etc., which have cheapness, practicability, and real merit to commend them. As I am somewhat engaged in the manufacture and sale of hives, etc., using and advocating the Simplicity and chaff hive, I am interested in their being as near perfect as it is possible to make them. The chaff hive, as far as I can see, has but one objection as to the manipulation of the frames; that is, having the frames in the upper story run crosswise of the lower-story frames. This subject, I know, has been brought up many times; but I have never seen it settled to my satisfaction. Almost every one that I have ever talked with upon the merits and demerits of the chaff hive raises this objection. Friend Stansbury, of Long Bottom, Ohio, made me a short call a few days ago, and he objected very strongly to this feature of the chaff hive, and thought it a great detriment to its use. I think I have arrived at a solution of the problem; and though it may not be entirely new, I have never seen it mentioned. It consists of a movable box inside of the upper story, made of about ¾-inch lumber, and of same inside dimensions as the lower story, which makes about 20 in. long by 15¾ wide. In fact, a Simplicity body, if a trifle short, will answer the purpose admirably, especially if the upper story of the chaff hive is, in turn, a little long. This inside story being only about 16 inches in width, leaves ample room to get the hands down at the sides to catch in the handholds to raise the story out of the hive. Now place your frames in this and you have as near a Simplicity hive inside of a chaff hive as you would wish. If you would utilize the vacant space left, you can easily arrange it for a single brood-frame at each side, and give the bees access to them. But I think the box will give sufficient room for most localities.

Now, any one can see that the tiering-up system, of which Mr. Heddon is so earnest an advocate, can be easily used by making a thin upper story for the chaff hive, just high enough to admit of another box or Simplicity body being placed on top of the one in the upper story of the chaff hive. The advantages of this system are, that free access can be had to the brood-chamber, and no necessity for having 10 wide frames standing around in every direction while you perform the necessary manipulations.

But there are seldom great advantages without some disadvantages. The only disadvantage, so far as I can see, is, that when the upper and lower frames are fastened together with comb, the lower frames (especially if metal-cornered) will sometimes follow the upper story when it is lifted out, and there is no way to loosen them as in the Simplicity. But I think if they are adjusted so as not to have over ¼-inch bee-space there will be no trouble. I think, also, that a modification of the Heddon honey-board could be used advantageously.

Now, friend Root, do not bring in the verdict of "too many contrivances, contraptions, etc.," for the hive need not be changed in the least. Although I have not put this into practice yet, I believe it will be a success, and therefore submit it to the bee-keepers for trial next season. This plan lessens the cost of a complete hive, as it dispenses with three wide frames, and requires only a cheap body instead.

MY REPORT.

As yet I have seen no reports of this season's work from this section of Ohio. I suppose one reason is, that there are no reports to make. The freezing weather of last winter, while there was no snow on the ground, resulted in an entire failure of the white clover, and therefore a failure of the honey crop. My report is about as follows: Increased from 18 to 25, and doubled back to 21; took four sections of honey, worth about 10 cents apiece, and extracted about 50 lbs. of sumac honey. I shall have to feed about 100 lbs. of sugar. I suppose this is about as good a report as any bee-keeper in this section of the country can give. We hope for a better season next year.

QUEENS HATCHING FROM THE CELL WHILE EXAMINING THEM.

I had a rather unusual occurrence in the queen-hatching line this summer. While waiting for an after-swarm to settle I opened the hive from which it issued, to save some queen-cells. The first cell I came to I laid upon a hive near by in the shade. While looking further I happened to glance around, and I saw a queen running around on top of the hive where the cell was laid. She was caged, and further search resulted in finding two more cells in which the queens were pushing the caps up so with their heads that I had to hold the caps down until I got them caged. Three queens hatched within three minutes. E. E. CROSS.

Racine, Meigs Co., O., Nov. 26, 1885.

Friend C., this matter has been up before, and I believe quite a number of the friends have been using Simplicity hives in the upper story of a chaff hive. Heddon's slatted honey-board would probably help us entirely over the difficulty of having the upper and lower frames built together; in other words, enable us to lift out the upper story at any time without trouble. You will need to take into account that you thus reduce the capacity of the upper story of the chaff hive. Instead of having 80 sections to fill, you have only 56 sections, and a strong colony will very likely fill the whole 80 about as quickly as they would the 56.

FEW OR MANY COLONIES: WHICH?

SHALL WE HAVE A FEW BEES IN MANY HIVES, OR MANY BEES IN A FEW HIVES?

WHILE reading the quotations from Peter Henderson's "Gardening for Profit," found on page 782 of GLEANINGS for 1885, I fell to wondering if a lesson could not be drawn from it for many of us who think we are on the right road to successful apiculture. There seems to be a growing tendency of late to multiply our number of colonies, rather than see how good results can be obtained from a few. In other words, we are using four acres of land, and expending more labor, to produce the same results which Peter Henderson's man achieved on his one acre. The question which arises is, Can or can not the bees be worked on the same plan, so that 50 colonies will produce as good results, with less labor, than is gotten from 200 worked in the way many apiaries are worked? I believe they can, and think the day is not far distant when one colony will be made to produce as good results as two are now doing, if they do not equal four. I have carefully watched the papers for the past few years, and I find it not uncommon to find where 50 colonies of bees are reported to have produced 5, 6, 7, and even 8000 lbs. of honey, while I have yet to see a report quadrupling such where four times the number of colonies were kept. I oftener find that 200 colonies give but little if any better results than do 50, while I know that more work is required to care for 200 during a year, than is required for 50. To this work we have to add the extra expense of hives, sections, etc., together with the large amount of honey it takes to feed those extra 150 colonies. This last, in my opinion, is wherein lies the main trouble in making a large number produce as many pounds per colony as do a few. From careful experiments and observations I am led to believe that it takes at least 60 lbs. of honey to carry one colony of bees through the year; hence if we get only 30 lbs. from a colony (an average yield that some bee-keepers say they are satisfied with), we get only one-third of the honey our bees gather, to pay us back for all our labor and capital invested; and also one-third of the product only, of our field. This product of the field can not be overlooked, as I have every reason to believe, from the past season's experience.

A few years ago I was enabled to get an average of 166 lbs. of honey from each of 67 colonies of bees, as the average result of a single season. This caused a great excitement in my neighborhood, and many went into bee-keeping, until I could count over 500 colonies of bees within a distance of two miles of my house, the result of which was a gradual lessening of the surplus honey per colony, so that little more honey in the aggregate was obtained from the 500 colonies than I obtained from the 67. The past winter reduced the number of bees by about three-fifths; and the result was, that during the past season my average per colony was about 120 lbs. of surplus, and the aggregate amount of surplus about the same as from the 500. At 60 lbs. of honey as food for a colony, it will take 30,000 lbs. for 500 colonies. To this add a surplus of 15,000 lbs., which is about what was obtained where the 500 were kept, and we have 45,000 lbs. as the product of our field, two-thirds of which was consumed by the bees. This season we had but about 200 colonies on the same field, which consumed only 12,000 lbs. for their wants, leaving 33,000 lbs. as surplus. As the 200 gave about 120 lbs. each as surplus, or 24,000 lbs., we have 9000 lbs. going to waste for lack of gatherers, thus giving 250 colonies as about the right number for our field, providing that 120 lbs. is set down as a surplus with which all should be satisfied. But I claim that our bees can be so worked that 200 lbs. can be secured as a surplus from each old colony in the spring, in which case 175 colonies would be sufficient for our field. Now, I candidly ask the reader if we had not better keep the number in our field at 175, thus securing 35,000 lbs. of the 45,000 as a surplus, rather than keep 500 colonies and get only 15,000 of the 45,000 as pay for our labor, letting the bees consume the rest. In other words, can we not make a few bees do for us what the market gardeners of the large cities make a small piece of land do for them; namely, get as much profit from an acre of land as some of our county people do from their tens of acres? I know this line of reasoning can not be made mathematically correct, yet there is in this thing a large and unexplored region well deserving of our best thoughts and efforts. Who will be the first to work it out for us practically? G. M. DOOLITTLE.

Borodino, N. Y., Dec., 1885.

Friend D., I agree exactly with you in this matter. The mania for rapid increase is oftentimes a very sad one, and beginners often seem to think it is a great thing to be able to say they are the owners of 100 or 200 colonies. Over and over again have I seen men who could winter 25 or 50 colonies, almost without loss, get demoralized, and fail, when they got up into the hundreds. It is not a very difficult matter to go over 25 colonies and put each and every one of them in the best possible shape for winter; but when it comes to undertaking to do the same thing with 100 or more, even the best of us are liable to get demoralized, as it were, lose our energy, and fail. By looking over the back numbers of GLEANINGS, especially the department headed Reports Encouraging, we find reports without number where some one, comparatively new at the business, has secured surplus in astonishing quantities from a small number of stocks. These same individuals, when they get a large apiary on their hands, find that it is next to impossible to obtain the same results per colony, even if the locality would give it. I have myself secured over 300 lbs. surplus from a single colony. Now, an apiary of even 25 colonies, each and every one of which was made to do this, would afford a pretty fair income, and the labor to get it from 25 hives would be nothing like going over 200 colonies. I believe it would be pretty good advice for all of us to keep our bees in few hives; keep crowding them back, and discourage increase; and then when winter comes, instead of having 100 hives with bees enough in the whole lot to make only 10 good colonies, we should have, say, 25 hives with bees enough in the 25 to make 50 ordinary colonies. You know I am one of those who never yet saw too many bees in a hive at any time of the year.

A HINT ON INTRODUCING.

DISTURBING THE COLONY AFTER HAVING LIBERATED THE QUEEN.

THE case of O. P. Phillips (see No. 21, current Vol. GLEANINGS), calls to mind my own experience. I have learned that the bees must not be disturbed, neither at the time nor soon after the queen is liberated. Having learned this by sad experience I devised a way to do it on the sly. I place the caged queen between the frames, pressing them to it tightly, to hold it in place. To the stopper in one end of the cage I attach a strong string, and pass the end through a small hole made in the end of the hive (I use the Langstroth). After leaving this at least 48 hours I draw the stopper by the string in the night, and do it so quietly the bees will not know any thing has happened, and all is well.

It will be seen that this plan is much the same as that given by E. M. Hayhurst, at the late meeting of the Western B. K. Association at Independence, Mo. The reason these precautions are needed is well stated by him (see GLEANINGS, p. 770): "If the bees are disturbed before the queen begins to lay she will become frightened, running and piping, and the bees will chase and kill her." He says, "Before she begins to lay." I had one balled this summer *after* she had been laying, because of the bees being disturbed by my search to see if she was all right. I have never failed with the plan I have given. J. T. GODDARD.

Muscatine, Ia., Nov. 27, 1885.

Friend G., I am well aware that bees often attack the queen, and sometimes kill her, just because the hive is opened, and they are stirred up about the time the queen is liberated. But I am also sorry to say, that they often kill queens where the cage is opened by pulling a string, or by letting the bees eat out the candy, or in other ways where the queen is liberated quietly. We have never found any way to answer so well in the long run, as liberating them by the Peet-cage plan; but even then we always think it best to look the colony over, and see how things are getting along. If the queen is killed we want to take immediate steps to put in another. If she is balled, give the colony a good smoking, and keep it up until they behave themselves. If she is all right, just as soon as you discover she is so, close the hive very quickly, and then let them alone.—By the way, I must say once more that I think the metal corners which so many object to, very greatly facilitate opening a hive and closing it, without getting the bees stirred up. When we can open a hive so quickly that no bee thinks of stopping his work, we certainly are not doing very much harm.

EGG-LAYING OF QUEENS

A MATTER OF VOLITION, AND NOT AUTOMATIC.

IT will be remembered that the greatly lamented Mr. Samuel Wagner suggested that the queen was merely an automaton as to laying eggs, whether they should be worker or drone eggs. He suggested that the mechanical pressure of the small worker-cells so compressed the spermatheca that the sperm-cells were forced out, and brought into connection with the germ-cells. On the other hand, the larger drone-cells would not exert such compression, so the spermatoza would not be extruded from the spermatheca, and so the eggs would leave the oviduct unfecundated, and so would develop into drones, or males. We know now that this view is no longer maintained. The muscular arrangement for forcing the germ-cells out of the spermatheca; the fact that worker-eggs are often laid in cells which are hardly more than commenced; the fact that impregnated eggs are laid in the large queen-cells; and the further fact that young queens, when they first commence laying, before they have fairly "learned the ropes," as it were, very frequently lay quite a number of drone-eggs in worker-cells. All this is more than enough to convince us that the adding or withholding the sperm-cells from the eggs is merely a matter of volition with the queen. It is probably true, that young queens desire and mean to lay only worker-eggs in the worker-cells, as they rarely lay any other the first months of their existence; but lack of experience, and awkwardness in managing the delicate muscular apparatus of the spermatheca at first, cause a few slips in the early work of egg-laying; hence the scattering drone-brood, which results from a few of the first-laid eggs of young queens.

That eminent English statesman and naturalist, Sir John Lubbock, has recently given some facts that have interest in this connection, and can not but interest every reader of GLEANINGS, as they have me. As is well known, wasps are very closely related to bees in structure, and in their physiological economy; hence any fact in regard to wasps may be, *should* be, considered and studied by the bee-keeper as of importance in his work and study of his little servants.

Sir John finds, that when a wasp provisions her nest with spiders of the same kind she always takes the same number. Wasps of different species take more or less, according to the size; and, strangest of all, the mother-wasp invariably places more insects in the cell with an egg that is to produce a female, than in a cell with an egg that is to produce a male. The female wasp is the larger. Here we see that the mother-wasp not only knows the kind of an egg she is to lay, but she provisions the cells with exact reference to the necessities of the case.

Who shall be so prejudiced as to say that her waspship does not consider her act in laying the special egg, and does not think and plan in maternal acts looking to the larders of her yet unborn? Now, if a wasp realizes what she is doing as she adds or withholds the sperm-cells, to such an extent that it influences her daily acts, and modifies her performance of daily duties, who shall say that the queen-bee, of higher development and structure, does not think upon her act as she places the eggs in drone or worker cells? So we have here another proof that egg-laying, with the queen, is a matter attended with intelligent volition; and far be it from me to say that the queen does not consider the size of her home, the population of her family, and the dimensions of her larder, as she passes in stately mien over the combs, stocking the worker or drone cells as circumstances dictate. If volition and discretion are exercised, we can easily see why the affairs in different hives vary. Each queen has her own notions. A. J. Cook.

Agricultural College, Mich., Dec. 15, 1885.

ANOTHER USE FOR HONEY.

EGGS NOT HATCHING; WINTERING.

IN the *Medical Times* for Nov. 28, 1885, in its Paris letter, written by Thomas Linn, M. D., there is given an important new use for honey, discovered by Dr. Comi, of Rome, by which the human body can be preserved for many years with its "natural color, form, and consistence.

"To preserve organic bodies in a flexible state, all that is required is to steep them in honey, the finest and clearest that can be found. The cephalic, thoracic, and abdominal cavities must be filled with tannin. The result obtained here is due to a sort of fermentation, alcoholic in its nature, that keeps the parts for a long time: afterward they harden."

The above facts are given on excellent authority, and are doubtless reliable.

EGGS NOT HATCHING.

A little more than a year ago I returned to you a Howard queen-daughter, with the statement that "her eggs would not hatch." Within a week after I wrote you, "Her eggs have been, *since her removal*, hatching."

About two months since, I came across a queen in my apiary that was fourteen days old, with a large patch of eggs deposited in one comb, and I marked her "laying." A week after that I again examined the colony, and was surprised to find there was no brood nor larvæ sealed; but again, I saw a good space filled with eggs. I waited again a week, having in remembrance the queen I returned to you, and hoping her eggs would finally begin to hatch; but at the end of this week I again found only eggs; and on Nov. 4 I killed the queen, to be followed by regret that I had done it, when, on Nov. 8, I found larvæ and queen-cells started, which duly matured, but too late, I fear, for the fertilization of the young queen. I believe such cases have never been published before, but I am without any doubts as to all the facts given above. I do not know what became of the eggs, whether they hatched and were immediately carried out, or eaten by the queen, workers, or drones, until the removal of the queen inclined them to a more sensible course. I am inclined to think that this is the explanation, for there was not more than one larva to five eggs which the queen left in the comb at the time of her removal. The colony in which this has just occurred was a very strong Palestine stock, entirely too wicked to "fool" with until after I had destroyed a virgin queen which had accidentally been allowed to hatch, and destroy the "grafted" Carniolan cell; since that they have been comparatively easy to manipulate. The colony has to-day several hundred drones in it, and I fear a virgin queen, for there has been only one day when any number of drones have been flying, and then the queen was but three days old.

PREPARING BEES FOR WINTER.

I have no new thing to offer on this subject; but judging from the many colonies lost every winter in every section of the United States and Canada, because of ignorance or carelessness on the part of apiarians, I think the cardinal points of the subject should constantly be presented in Gleanings. There are three of these.

1. Contraction. This is never to be neglected where a hive as large as the Simplicity is used. If the colony is one of the strongest, I would remove three of the lightest combs and substitute division-boards. If the colony is weaker, remove enough frames to *crowd* the bees on the remaining combs; or if the colony will only fairly cover one comb, remove all but one comb.

2. Stores. In this provision the important thing to attend to is to see that there is an abundance. Give me a single comb as full of pollen as you can get it, and I will take enough bees to thoroughly cover it, have them store syrup over the pollen by building out the comb, and I will insure as good wintering of the colony as can be had with any other stores. As food, I should prefer granulated-sugar syrup to honey; and as I can always sell honey and buy sugar with profit to myself, I never feed honey back.

3. Ventilation. As illustration, take four colonies, like the very weak ones referred to above, there being only enough bees in each to thoroughly cover one comb, and this one full of syrup as directed above. I take a two-frame nucleus hive, make through its center a division by means of new enameled cloth, place a colony with one frame on each side of the division, covering each with two folds of strong canvas. I prepare another nucleus hive as above, but remove the bottom, placing this one on top of the other one, but with its entrance reversed. I pack them both, with their four queens and retinues, in a box with ten inches of space on every side, preparing entrances ⅜×1 inch, diverging toward the outside so that they will be ten inches apart. I will now carefully pack them with chaff around and above, and leave them undisturbed out of doors all winter. Of course, it must be seen to that the roofs do not leak, and a hole should be made at either end of the box just under the lid that would admit air but not rain. If the packing of these nuclei is undisturbed, the same principles can be easily extended to the larger colonies. It is not unusual to experience a temperature here of 4 to 5° below zero; hence in this latitude I am not in favor of cellar wintering; but if I were in a much colder one I should be. I winter strong colonies in the single-walled Simplicity hive, without any packing, except to replace the enameled cloth above, with a chaff cushion, having only attended well to the two first cardinal points; viz., contraction and stores. If there is but one nucleus colony

in the apiary, put it on one comb in a hive having space only for one comb; pack it in a box with ten or twelve inches of chaff all around, above and below, and it, too, can be saved. I have tried these experiments for ten years past, and I know wintering bees can thus be made successful, even when the colony is but a nucleus. I have 50 colonies in my Carniolan apiary. S. W. MORRISON, M. D.

Oxford, Pa., Dec. 7, 1885.

Friend M., the fact you mention in regard to the preservative power of honey corroborates what friend Muth says in reference to its use for pork-packing, if you will excuse the illustration.—What you say about eggs not hatching has been up once or twice before; but I believe we have no good explanation of the reason why eggs sometimes fail to hatch for quite a time, and then all at once begin to develop larvæ all right. Friend Doolittle wrote an article on a similar subject some years back.—I agree with you in regard to preparing bees for winter; but we have not been successful with two-frame nuclei, even when prepared very much in the same way in which you direct.

AN A B C SCHOLAR'S EXPERIENCE.

17 DAYS FROM THE EGG TO THE BEE.

I WAS but a novice in the spring. I never owned a colony of bees before, but by the information of GLEANINGS and A B C I have increased from 1 to 3 by artificial swarming. I commenced very late, on account of the weakness of the old colony, then being careful not to lessen the old stock, in my judgment, below thirty thousand, so as to have surplus honey for home use. I was reading and putting this to practice, and I found no deviation but this; you say: "Twenty-one days elapse from the egg to the bee." Well, here is my experience: I put down the date of every thing I undertook. June 24th I placed two empty racks, without foundation, in the old hive, and took them out July 13th, and young bees were coming out of their secluded spot, and moving among the busy throng while I held the racks in my hands, and there was evidence that some hatched a day, or perhaps several days, before near the top-bar of the rack, and had been replaced with eggs, so this makes but 19 days, and perhaps 17 days, from the egg to the bee, although you say there are exceptions.

Now, here is the question: I see two colonies are full below of beautiful capped honey, while the last one is full with comb, but none capped, so I gave them a rack of capped honey from another hive, and, to my surprise, I found that they uncapped every cell and removed most of the honey, and the queen laying in them. Why is this? Can they winter safely in this or not? S. R. BRINER.

North Springfield, Ohio.

Friend B., I do not know where the mistake comes in; but I am just as sure you made a mistake, as if you had told me you planted corn one day and it was up two inches high the next day. As you state it, it seems very hard to tell where the mistake came in; but these dates are so well established, by thousands of careful experiments, that I should think it more probable somebody swapped those combs without your knowledge, than that a perfectly formed bee was hatched in the time you mention. Of course, it does not seem very likely any one would meddle with the combs in your hives; but you know it is possible. Try the experiment again, and see if I am not right. Exceedingly favorable circumstances may shorten the period perhaps 24 hours. The way to count is to mark the very hour the queen laid the eggs; and then watch when these same eggs produce perfect bees.—Bees will very frequently uncap the honey when a frame of capped honey is put into the hive. They are more likely to do this when they have no capped honey of their own. I do not know why they do it, unless it is because they recognize it is not their own work, and they want to look in and see if it is all right. Young bees, which have not much to do, are particularly up to such tricks.

SOME GLEANINGS FROM GLEANINGS.

WHEAT CHAFF; CLIPPING QUEENS' WINGS; SOLAR WAX-EXTRACTORS.

IN GLEANINGS for Nov. 15, p. 766, Ernest speaks of the difference in value of oat and wheat chaff. This point, which he just brought up, is exactly the one which I have told in your and other journals. My experiments proved, many years ago, that there is little or no difference in the various kinds of chaff so far as protection from cold is concerned; but the difference is very marked as regards retaining the moisture thrown off by the bees. I find the different kinds of chaff are valuable for this quality of not retaining moisture, in the following order: Timothy, wheat, oats, and buckwheat chaff.

TWO QUEENS, NOT RELATED, IN ONE HIVE.

On the same page Mr. Broers, in speaking about two queens in a hive, takes it for granted that they are both the original queens that were hived with the swarm in April. As no observations were made in this case between April and October it is more than probable, in my opinion, that both of these queens were not the same ones seen in April, but that one of the queens seen last was a young queen raised late in the season, to supersede the other. The fact that the queen being superseded was less than a year old, and a perfect one, is no reason why the bees might not be superseding her, as they occasionally act on just such foolish notions as that would be.

DISTURBING HIVES AFTER A QUEEN HAS JUST BEEN INTRODUCED.

I see, on p. 770, that even as accurate an observer as our friend Hayhurst usually is, he makes the old statement about the danger to a lately introduced queen in opening the hive before she has got to laying. I have never yet known of having lost a queen under these circumstances, although it has been my general practice for years to open hives the first opportunity I have after introducing my queens, and I have certainly opened scores of them before the queens commenced to lay. I presume, however, that the manner of opening the hive has something to do with it. I certainly shouldn't open them, if the frames were stuck so they would have to be pried apart with a chisel, nor if robbers were about.

CLIPPING WINGS—HOW.

I also see, on p. 773, that friend Doolittle still advises catching the queen with the fingers while clipping her wings. I have clipped the wings of certainly more than a thousand queens with scissors, and have clipped off just one leg of a queen while doing so, and I have no fears of such a "happenstance" occurring again. I couldn't see in that case that the loss of a leg caused the queen to become less valuable; but even the accidental clipping-off of a leg is not advised. It is now years since I abandoned the method of holding queens with the fingers while clipping their wings, and I think that no one who gives tweezers a fair trial will ever return to finger-catching. I use, for that purpose, a pair of sharp-pointed tweezers, such as jewelers use, with which I catch and hold the queen by a wing while clipping. You keep the right kind of tweezers for this work on your ten-cent counter; but only the ones with sharp points are suitable for this work. I have described this way of using tweezers before; but if Mr. Doolittle has overlooked it, many others must have done so too.

SOLAR WAX-EXTRACTORS.

On p. 775 friend Israel, of California, describes his solar wax-extractor, which is on the same principle, but not so good, as the one I described nearly three years ago in GLEANINGS. That old sacking he speaks of laying in the bottom of the extractor, and which seems to be such a favorite idea with many, is not only absolutely unnecessary, but would almost ruin the efficiency of the instrument in the latitude of our Northern States. It will work better, of course, in California, or any of the Southern States; but even there it is more damage than good. In our Northern States we have to utilize all the heat from the sun's rays we can, and we can not afford to let old sacking or any other unnecessary article absorb any of the heat. The object for which the sacking is used is arrived at by dipping off the melted wax, as described in the original article referred to (page 521, 1883).

Another mistake made by friend Israel, I think, is in allowing the wax to remain in the dish, or receiving-pan, for several days, instead of removing each day. Wax becomes perfectly clarified in a single day, and any further exposure of it to the sun simply results in hardening and bleaching the wax. I have used these solar wax-extractors about ten years, and am foolish enough to think I know something about them. I was in hopes, when I wrote my first description of them, that they would be materially improved by some one; but so far, all published experiments seem to be in line with the one we have just criticised. What is wanted, in the latitude of Northern Iowa, at least, is some device for increasing the power of the sun's rays, and not something that will absorb some of those rays. I wish, friend Root, that whenever a description of some straining device is sent in, you would call attention, in your foot-notes, to the fact that, while such devices are practically unnecessary anywhere, they are a positive damage in the latitude of our Northern States.

WHERE IS HAWK'S PARK?

Quite a number of bee-keepers have asked me, both verbally and by letter, "Where is Hawk's Park?" "How far from New Smyrna?" Hawk's Park is a newly established postoffice about three miles south of New Smyrna, in Volusia Co. Nearly or quite all the bee-keepers in this section used to get their mail at New Smyrna, but about a half of them have changed their mail to the new office. Messrs. Sheldon, Detweiler, Dr. Goodwin, Lewis, and others, are at New Smyrna, while Hart, Hardee, Oleson, Mitchell, Packwood and others are nearer Hawk's Park. Both places are on the shores of the Hillsboro River, or lagoon, a sheet of tidal water, and about two miles in a direct line from the ocean-beach. Steamers come into the river from the ocean at the inlet, some seven miles north of this place.

O. O. POPPLETON.

Hawk's Park, Fla., Dec. 7, 1885.

Many thanks, my good friend P., for your kind suggestions and criticisms. No doubt we have overlooked the facts you gave us in your former valuable paper, but we will now try to "make a note of it," so it will not slip our memory so easily. We shall proceed at once to make experiments in regard to solar wax-extractors.

ALMOST BURIED ALIVE.

A STORY WITH A MORAL TO IT; LAYING TILE.

I AM feeling tolerably stiff and sore this evening, but will give you an item of interest. I am now laying a 10-inch tile from the north-west corner of my 8½-ft. cellar that is dug in a dry bank of sand. We found evidence that the blue-grass sod and hard streak of clay at the top had not wet through this summer or fall. The dirt, or sand, after it got two or three feet from the top of the ground, was as dry as it would be were it under a good roof, for nearly a rod from the house, then it got damp, when it made a "cave" on me. I was down on the tile that was laid, on my hands and knees, when it struck me without warning. We were nine feet deep. I tell you, I thought I was going to be buried alive; for as the weight of the sand increased, it moved me flat down on the tile that was under me; and when I did move a muscle it took up every particle of vacancy, so I soon thought I was in a tight place. Thanks to an active, energetic Irishman, a hand that was helping me, who was raised in the old country, and who knew how to shovel the few cart-loads of sand that struck me, I was got out before the rest of the bank fell in to about 6 feet deep. I say I was got out, for no one knows how a strong or tolerably strong man's strength is taken out of him till he is crushed under a few tons of bank sand.

I write this, as it has its own moral, though some may think it of no use to bee-keepers; but all do not work with bees only, who keep bees; some are farmers, as I am, who was raised on a farm, and have to do such work as his hands are not used to doing or can not do. We found the black ants 6 feet in the sand, where frost will never reach them, in great numbers. Where they had burrowed it looked like a very comfortable place for them to winter, so they could eat honey next summer. They ate lots of it, I guess, last summer, but they rather prefer the sugar-barrel, I think, to honey. I will close by saying we have over 100 feet of tile laid 9 feet at the house, running to 7 feet where we are now. I think we shall get in 200 feet. You would hardly think one man could throw out such a large pile of sand and dirt in three days. I have helped some to-day, but was bothered a good deal to have the tile carried to me and handed down (ditch 2 to 4 feet at top, and where it caved in it was some two rods). J. D. ADAMS.

Nira, Ia., Nov. 25, 1885.

Friend A., I should suppose, from the size of your tile, and the depth you were working, that you intended it for a sub-earth ventilator. My experience has been, that such sandy soils as you describe seldom need tiling at all, unless there are springs. I hope your experience may be a warning to our readers when digging in the ground at such a depth as you mention. In our clay soil there would have been no trouble. I hardly need say, that great numbers of good people have lost their lives in a manner similar to the one you describe.

SOME QUERIES FROM AN A B C SCHOLAR.

DOUBLING UP, ETC.

ERNEST R. ROOT:—I am so pleased that you have begun a series of articles, "Our Own Apiary," in GLEANINGS, that I am going to sit down and tell you so. I am just an A B C pupil in bee-keeping. I began with one swarm late last year. There is so much I want to learn, I am often puzzled to know the best way of managing my bees, and I think I wish I knew just how they would do in Mr. Root's apiary; for though I read most of the articles in GLEANINGS from different writers, it some way seems to me that Mr. Root's way is usually the most easily understood, the simplest, and most practical. And now your articles are going to be a help to me.

In your first article you say, "Doubling up has already commenced." Now, undoubtedly, that is perfectly understood by apiarists who know their business; but, will not Ernest, or some one else, through GLEANINGS, be kind enough to explain, for the benefit of myself and others just beginning, just how that is done—every little item precisely? Suppose you have two small swarms of cross hybrids in Simplicity hives, and you wish to unite them into a chaff hive for winter; what is the first thing —smoker, bee-hat, or neither? You can not get all the frames into the new hive. Do you alternate a part of them, and brush the bees from the remaining combs in front of the hive? Do you hunt out one queen and kill her, or let the bees do that? Would you set the chaff hive where one of the old ones stood, or in a new place? Very simple questions, no doubt, to one who has worked for years among bees, but not so much so to one who knows but little about them. Also please tell me, how do you know when a colony has stores enough for winter? How do you know when they have 25 lbs.? Guess at it? You surely do not take the trouble to brush the bees from every comb and weigh it, do you? Do snails do any harm to bees? After a swarm has filled the brood-combs, and you have put on one layer of sections, and they have nearly filled them, is it better to add more sections above the first, or remove the first and place new ones with foundation starters in their place? How do you get your extra frames of honey that you save in case the bees need them? Do you use a Simplicity hive on top of a chaff hive, and put brood-combs in these? When you want to form a nucleus, how far from the old hive must you place the new one? Which is better for packing—wheat or oat chaff? My husband says he thinks the wheat chaff would keep dryer, but it seems to me the oat chaff would be warmer.

I use the Falcon chaff hive, which is made at Falconer's, seven miles from here. It is packed with fine shavings, and so are the chaff cushions. Do you think shavings would be as warm as chaff?

I have not as yet made my bees very profitable. Increased from one to two last year, and wintered nicely. This season they increased from two to six, and took up about 70 lbs. of beautiful section honey. I am learning all the time, and I think I can manage them much better next year.

I am going to try Mr. Heddon's plan, and Mr. Doolittle's, for preventing after-swarms. I think either one will work nicely.

My only bit of bad luck with my bees so far is the loss, just before basswood-bloom, of my best swarm, and a tested queen I sent to you for. And, by the way, she was such a nice queen, and came through in splendid condition. Some four days before, I had taken three frames of bees and brood and put in a new hive. I put the queen on a frame of honey-comb in the cage, and hung it in the hive. In less than half an hour they had worked the comb away and let her out. In four weeks' time—perhaps two or three days over—they had filled 7 brood-frames and nearly the side sections, then sent out a nice swarm, and left a fair quantity of bees in the hive. I hived them and they seemed contented, and went to work. They stayed that day and the forenoon of the next; but toward night, when I went out to look at them, behold, they were missing. The weather was very warm, and the hive not shaded. That was probably the reason why they left—rather an expensive lesson, and I was so sorry to lose my nice queen! Perhaps if I had known just how, I might have clipped her wings at first; but it seems almost cruel to cripple the pretty creatures.

Notwithstanding directions for managing are plain in the A B C book, I often wish they were more explicit in little things which I suppose tact and common sense ought to teach me. Perhaps I am unusually dull; but I often think, "If I could only ask Mr. Root a few questions!"

I am much pleased with GLEANINGS, and like it much better because it is not wholly devoted to bees. My children enjoy the Juvenile department, and I read the children's sermons to them. The Home sermons are also read, and I feel thankful that at least one man is trying to prove to the world that religion is our daily life—not that I wish to be understood that there are not many more than one, but the ranks ought to be much fuller, both of men and women, who realize that, every day, home and business life should be our religious life.

I always read Mrs. Chaddock's letters. There is much lively human nature in them, and they demonstrate to me that other farmers' wives in the land are busy, and trying to make the best of surrounding circumstances, as well as myself.

I also feel that I should like to thank Mrs. Culp for her letters, teaching us Christian charity, love, and trust.

Count on me as a subscriber as long as my bees make honey enough to pay the subscription price.

Fluvanna, N. Y. SARAH M. BENTLY.

"Doubling up" is only another name for

uniting. The A B C under this head, page 271, gives the precise method of doubling up, or uniting, that we used in the apiary this fall. As to the rest of your questions, I will leave it to father, for it takes an old head to answer questions, though of themselves seemingly simple. ERNEST.

Many thanks, my good friend, for your kind words. I am glad, also, to know that you like the A B C book because it is so very plain, and goes into minute details so much. Some have objected to it on this account; but it seems you want still further details.—In regard to the use of smoker and bee-hat, use them if you find them a convenience, and I presume you will get along better with both, from what you say. In uniting, take the frames with the most brood and stores; and if there are still more containing honey, and the weather is warm, you can put these additional ones in the upper story. I do not think it matters very much whether you alternate a frame, or simply place the two colonies side by side. The most important thing is to be sure the bees do not get to quarreling; and if they do, you must make them behave by using smoke freely until they do behave. You can kill the poorest queen yourself; or if there is no difference, and you have no choice, let the bees do it.—I would set the chaff hive where the strongest of the old ones stood, and take the other hive entirely away, so the bees will not go into it and die when they fly again.—An old bee-keeper will tell by looking the colony over, and lifting the hive, whether they have stores enough; but until you have learned by experience, I think it an excellant plan to weigh them. You can weigh the combs one at a time with a pair of ten-cent spring balances, or you can weigh the whole hive, subtracting the weight of the empty hive and combs. You need not brush the bees away from the combs in order to weigh it. They weigh so little they need not be counted.—Neither snails nor hardly any thing else will harm the bees if the colony is a strong one.—We give the preference to the wheat packing, for the reasons you mention. Fine shavings, prepared just right, will probably answer nearly or quite as well; but all things considered, we have preferred the chaff. Had you given your new swarm a frame of brood, as we so emphatically advise in the A B C, I think you would not have lost them. — We do not practice clipping queens' wings now.

AN INTERESTING LETTER FROM AN A B C SCHOLAR.

QUEEN-CELLS BUILT IN A HIVE WITH A LAYING QUEEN.

WILL you listen to an A B C scholar a short time while he reports his experience with bees? In the spring of 1881 my father had two swarms of hybrids in L. hives. I became interested in them, and sent for an A B C book. I increased them to five colonies, but they were so cross I concluded that I must have Italians. I sent to you for five "dollar" queens. They came all right in Peet cages. I caged the old queens and fastened the new ones on the combs, as directed. The next day I looked them over, and found that they were all out, but I found something else which almost made me feel weak — every swarm had started queen-cells. Well, thought I, they are all dead; just my luck, exactly. I am glad I saved the old queens. I can put them back. There is some consolation in that. I put one of the queens among the bees, when one of them grabbed her by the wing and tried to sting. I caged her immediately, closed the hive, and sat down, completely "stumped." I didn't know what to do. Perhaps you can imagine how I felt. I can't describe it. I saw bees and queens all that night. The next day I thought I would try to give to another hive the old queen. I opened the hive, lifted out a frame, and right on the center was the new queen. She seemed, to my astonished eyes, to be about four times as large as the one I had introduced. She had commenced laying. I went to the other hives, and found the same condition of things. I looked in the A B C book, but I failed to find any mention of bees starting cells with a queen in the hive. On page 192 I found it said, that "it is a sure indication of queenlessness to find a nucleus building queen-cells." Well, thought I, this is not a nucleus; perhaps that makes the difference. All the queens proved to be purely mated and very prolific.

I have worked away from home since then until this summer, when, being at home again, and finding three swarms alive (one, by the way, contains one of those dollar queens, as lively and prolific as ever), and having lost none of my interest in bees I thought I would raise some queens and make nuclei of the old dollar queen's swarm, and build them up and so get more bees and experience. I have the experience; and unless I have some more unexpected trouble I think I shall get the bees. I followed the directions, and a couple of days before the cells were to hatch I divided up the old swarm, putting two frames of brood, covered with bees, into each nucleus. The next day I found that they had all started queen-cells, and concluded that the old queen must have got lost in some way. I inserted cells in each, and they waxed them all in; but they did not hatch. In five or six days they all had cells of their own building capped over, except one, and that one contained eggs and larvæ, so the old queen was all right after all. The only reason I can suggest for the cells not hatching is, that the next two nights after I inserted them were frosty, and they might have been chilled. Now, here are some questions: Why did the nucleus containing the old queen start cells, and why did they accept the cell I gave them, and wax it in nicely? Is the rule I have quoted from the A B C book incorrect, or do my bees act differently from every one's else?

A LITTLE STORY WITH A MORAL TO IT.

I am taking GLEANINGS, with one of my neighbors. I think it is "splendid," as the girls say. The criticisms from some of the friends make me think of what I saw in a village last spring. A man was fixing the sidewalk in front of his house. In a short time there were several men around him, telling him how to do it. He kept right on, and fixed it to suit himself. I guess that is the best way.

Rockwell's Mills, N. Y. ELMER D. CORNELL.

Friend C., it is very singular indeed that all five of your colonies built queen-cells while they had a queen, although it is not very unusual for a colony to persist in building queen-cells when a new queen has just been given them, indicating that *all* the members of the commonwealth are not quite satisfied to accept her. It is a pretty hard matter to have the A B C book touch all these minor points.—I do not think that frosty nights would injure a queen-cell if put right into the brood-nest, especially if the cluster of bees were enough to make a tolerable colony or nucleus.—The conditions of your little story are not quite like those of a bee-journal, friend C. The sidewalk belonged entirely to the man. He was not building it for his neighbors who were making suggestions. But a journal belongs to the people; in fact, it is made for them, and they have a right to suggest how it should be made. I am glad to say, however, that the general decision of the people seems to be just in accordance with my own; that is, by far the greater number of friends seem to prefer to have GLEANINGS with a variety, and, I believe, such a variety as I have given. That those who subscribe may not be disappointed, we have changed the front page of our journal so as to read, "Devoted to Bees, Honey, and Home Interests," so as to say we are not getting away from our text, even if we do touch on other industries as they come before the people.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER I.

INTRODUCTION.

IT was a lovely day, late in autumn. The Rev. John Meek had been in his study all the morning, busy at work on his sermons for the coming Sabbath. Looking out on that beautiful Indian-summer day he felt that a walk would do him good; and, picking up his hat and cane, he started forth to take one.

As he stepped through his gate into the highway he noticed some object up the road which he at first thought was a team approaching; but on looking more intently he saw it was not a team, but his two children running toward him at the top of their speed. His wife, noticing him earnestly gazing up the road, came to the gate to see what was the matter; and after a look at the children she exclaimed, "That is our Jane and Tommy. I sent them on an errand to Mr. Brown's. What can be wrong, that they are running so?"

By this time both children were crying out something to their parents; but the children were so short of breath from running, and so eager to tell the tale, that the parents could not understand them. However, they managed to catch the words, "Mr. Brown — bees — keg — killed — home!"

Mrs. Meek remarked, "I fear Mr. Brown's bees have stung him to death."

Her husband replied, "I hope not, but we shall soon learn."

By this time the children had arrived, and began to tell their story, both at once; but Tommy was told to stop and let his sister tell it. It was all about a colony of bees which Mr. Brown had offered them as a present. Mr. Brown was a friend and neighbor, living on a large farm not far from Mr. Meek's house. Although he kept a few bees he made no claim to understanding bee culture. His bees received very little care or attention from him. His hives stood in a row upon a bench in his orchard, and were merely rough boxes, some of which he made himself, while he picked up others around the village stores. He obtained his surplus by boring holes in the tops of his hives, and placing on these some smaller boxes. At the approach of winter, if any colony had not sufficient stores the bees in it were killed and the honey taken. Mr. Brown had been examining his bees that morning, to see what stores they had. He found all well supplied but one, which came off very late, and which, for want of a suitable box, he had placed in an old nail-keg. This one he decided to destroy, and was preparing to do so when the children arrived. His children explained to their little friends what their father was doing, and urged them to wait and have some of the honey. The kind-hearted Jane's eyes filled with tears as she thought of the poor little bees in the old keg, peaceful and happy, clustered as usual on their combs, but soon to meet a horrible death.

Mr. Brown's plan of killing bees was to smother them to death with the fumes of burning brimstone. As she watched Mr. Brown digging the brimstone-pit she ventured to say to him, "I hate to think of your killing the bees."

He replied, "I hate to kill them; but they haven't sufficient honey to support them through the winter. They will eat up what they have, and then die of starvation; and surely it is better to kill them now, and obtain some honey, than to let them starve and obtain nothing. I kill them to keep them from dying of starvation."

Jane asked if they could not be fed, and their lives preserved until spring.

Mr. Brown replied, "I believe some people do feed bees, but I do not know how it is done; besides, I have so many horses, cows, and pigs to feed that I can find no time to feed bees. But," said he, "I'll give you and Tommy this nail-keg hive, bees and all, as a present, if you will take them home, feed them up, and preserve their lives. Your father knows something about bees, because I have heard him talk about them, and he can tell you how to feed them."

Jane replied, "I would willingly take the bees, but I shall have to ask papa and mamma about it first."

"Very well," said Mr. Brown; "you run home and ask them, and I will not kill the bees until I hear from you."

The children certainly did "run" home, and, having related the facts in the case, stood waiting for the important question, as to whether the gift should be accepted or not, to be decided.

Mrs. Meek laughed heartily, saying, "Is *that* all? Your pa and I thought, from the way you ran, that something dreadful had happened; and now you say your reason for running was to obtain leave from us to keep bees. Children, I am sure you do not know what you ask. If you knew how bees sting, and how it hurts to be stung, I am sure you would not ask to keep them. I think you had better let Mr. Brown keep them."

"But, ma," said Tommy, "Mr. Brown will kill them. He said he would kill them unless we took them."

"Now, ma, think about the poor little bees being smothered to death with brimstone," chimed in Jane. Then, turning to her father, she said, coaxingly, "Please, pa, may we not keep them? Mr. Brown said we could have them, and welcome, and that you could tell Tommy and me how to take care of them."

Mr. Meek replied, "I was starting to take a walk, and the day is so fine I do not want to miss it. As I walk along I will think the matter over, and I will meet you at the dinner-table, when we will talk it over." With that he walked away.

While Mr. Meek studied his Bible and his books on theology very faithfully, he also studied about many other things. He had read several works on the management of bees. His father kept bees after the old plan, and when a boy he had become familiar with its workings. He thought it cruel to kill the bees in a hive to obtain their stores. In his travels since entering the ministry he had visited many modern bee-keepers, and noticed with gladness the advances which had been made. All the bees near where he now lived were kept upon the old plan. He had often talked to Mr. Brown and others about trying the modern improvements; but they had never been persuaded to try them. He often thought of buying a colony and showing the people around what modern bee-keeping is, in hopes that they might be led by his success to adopt some of the improvements. He knew that the country afforded plenty of bee-pasture. White clover, that best of all honey-plants, abounded along the roadsides and in all the pasture-fields and meadows. He was certain that many thousands of pounds of honey were wasted every year, near his home, for lack of bees to gather it. He also believed it would benefit the children, to have the care of bees. He said to himself, "They will learn something, even if this colony does not live until spring."

His conclusion was, that the children might accept the offered gift. He understood very well why tender-hearted Jane pitied the bees in the doomed hive. When a boy, he himself had often shed tears over the unhappy fate of similar colonies when he saw them placed in the brimstone-pit. As Jane was only ten years old, and Tommy eight, they knew very little about any kind of work, and nothing at all about working with bees. They would need much counsel and help, which he was willing to give, provided they did their part cheerfully.

As they sat at the dinner-table the children were very impatient to learn the decision; but having been well taught they waited for their parents to introduce the subject. At length their father remarked, "I think Mr. Brown's offer a very good one, and we had better accept it."

Jane said, "Oh! thank you, papa; thank you, papa!" But Tommy dropped his piece of bread and butter, and, clapping his hands together, said, "Good! good! good!"

It was always his custom, when much pleased, to dance around on one foot, clapping his hands together, exclaiming, "Good! good!" but as he was now sitting at the table he could not very well indulge in the dance on one foot.

Mr. Meek continued, "I allow you to accept the offer, for various reasons. One is, pity for the poor little bees doomed to die. They are now under the sentence of death, and will be killed unless we take them and save them. Another is, that you children may learn how to keep bees. The art of bee-keeping is a trade. If the bees live, and you care for them, you will learn this trade; and the knowledge you will thus acquire may be very useful to you in after-life. Another reason is this: I should like to set before our neighbors and friends the example of a well-kept bee-yard. I am sure that many colonies of bees might be kept in our vicinity; and I think if I could show the people how to keep them profitably, I might advance bee culture in this neighborhood. And now, Jane and Tommy, I want you to remember that Mr. Brown gave the bees to *you*. *You* are the owners of them; *you* are the bee-keepers, and *you* must do the work. *I* will direct you what to do, and will help you do what I think too hard or too difficult for you. You must, in return for my services, furnish us some of your honey for our table."

We can not record all the conversation which lasted through the meal, and was continued after they had left the table. They then went out into the yard, selected a spot where the hive should be placed, and prepared a stand on which to place it. Then the question arose, how best to remove it. Mr. Meek's advice was asked. He said, "There is in our barn a large sack. It will hold a nail-keg nicely. Take it, put the keg into it, then tie it securely. Take the buggy, place the keg it the buggy, and drive carefully home, and not a bee can escape to trouble you. When you place the keg in the buggy, be sure to turn it bottom up, and then the combs will not be so likely to break."

Thus equipped the children drove away about sundown, and a little after dark a shout at the front gate announced that they had returned with their precious load. Mr. Meek went out, and carried in the hive. He thought it best not to open the sack nor place it on the stand until all the bees had crawled back into the hive. He placed it in a position favorable for their doing so; and in the morning, all being quiet in the hive, the keg was gently drawn from the sack, and placed upon the stand. Mr. Meek pronounced it light in stores, the combs not filling more than half the keg.

"They must be fed," said he; and as it was now late in the season, no time was to be lost. The children prepared feed after directions given by their father. They possessed a dollar, which they expended for granulated sugar. They then made this into a thick nice syrup by adding some water, and heating it. A tin pan was borrowed from their mother, filled with this feed, a little warm, and the surface of the syrup was covered with little strips of pine, split from the kindling-wood, to keep the bees from drowning in it. Jane then stood behind the hive and gently tipped it back, while Tommy slipped the pan of feed upon the bottom-board; the hive being then let down he covered it and kept out robber-bees.

In the evening the children took the horse-blankets and the buffalo-robe and covered the hive, completely protecting it from the cold, and enabling them to take up the feed. The feed was always warm when placed in the hive; and being thus protected it was all taken by morning. They were thus fed repeatedly. When the dollar's worth of sugar had been fed, Mr. Meek said, "They surely will do until spring, when they can be fed some more if they need it. Now," says he, "they can remain here until the severe weather comes, when we must place them in their winter quarters."

To be continued Feb. 1st.

C. C. MILLER'S REPORT.

TEMPERATURE OF CELLARS AND OF THE EARTH.

As Mr. Root (p. 812) inquires how I succeeded in carting my bees around, and about the honey and money I made, I will try to answer in full. First as to the success of carting around, I consider it a matter of necessity, and would not think of keeping all my bees in one apiary; and as I winter in cellar I am obliged to haul home the bees every fall and take them away in the spring. This I have done for six years, but I never hauled them away at any other time, except in the summer of 1880, when I took them three miles to the edge of a large buckwheat field. I think they did enough better than those left at home to pay for the hauling.

Now as to the result of the year. I'm not proud of it. I don't glow with pride as I contemplate it. Never a glow. Nov. 5 to 12, 1884, I put my bees in the cellars, 300 colonies. March 28, 1885, I began taking them out, and took out the last April 13, making a confinement of 126 to 159 days. By the time fruit-trees were in bloom I had 179 colonies left, a loss of about 40 per cent. I increased these to 340 colonies, and took about 1700 lbs. of comb honey, making 9½ lbs. per colony, and 90 per cent increase. I might theorize and philosophize as to why 40 per cent should have been lost in wintering and springing, but I will try to limit myself mainly to what I know. There were some plain cases of starving—not a drop of honey left in the hive. The winter was very cold—37° below zero at one time, and the cellars were allowed to become quite cold. In one of them the mercury reached one degree below the freezing-point. I will allow myself to theorize far enough to say, that a smaller number in each cellar would have done better—at any rate, they wintered better in former years when not so crowded. I can not tell just how many were alive last spring when taken out, but I think the heaviest loss occurred after taking out. Some dwindled, and some swarmed out. Some of the latter seemed pretty fair colonies, and the deserted hives showed plenty of honey left, and also of brood—perhaps more brood than the bees could cover.

Mine is not a good honey region, white clover being about my only dependence for surplus. Last summer the clover bloom was more abundant than I ever knew it, but for some reason the honey was not forthcoming. When the flow of honey was over, many colonies had scarcely any honey, and one actually starved to death—a thing I never experienced at that season of the year before. I ought to have mentioned, that a great many colonies were very slow about building up in the spring and summer. Soon after the failure of clover I began to feed syrup of granulated sugar, and in all I fed about 1700 lbs., to make them ready for winter.

TEMPERATURE OF CELLAR.

I read your remarks, Bro. Root, on p. 830, with some surprise. You say, replying to J. F. Redd, "Your cellar will very likely run from 58° to 60° in spite of any thing you can do," etc. Is it possible there is so much difference between your place and this, in latitude 42°? I am not sure that I ever knew the thermometer in my cellar to run up to 60° when there were bees in it. I happen to have before me the record of the winter of 1876-7, in which the thermometer ranged as high, or higher, than the average. Dec. 10 it was 35°, and was no higher than 41° till Jan. 29, when it reached 42°, going no higher than 46° till April 1, when it stood at 49°, the highest point it reached during the bees' confinement. So you see in this region there seems little difficulty in keeping below 58° or 60°, and I do not now so much wonder that you prefer outdoor wintering in your locality. I think it is pretty well agreed, that, for best results, a cellar should be kept at about 45°; and the testimony agrees so generally on this point that I suppose for the majority of persons and places it is correct; but I have never succeeded in keeping my cellar to average more than 40°, if that. Indeed, it has taken a good deal of artificial heat to keep it up anywhere near that point. I am not sure whether 5° warmer would be any better; for in the winter already mentioned, 127 colonies were put in, in the fall, and 127 taken out in good condition in the spring; still, three were lost in springing—whether from queenlessness or otherwise, I can not now say. Probably the best plan is for each one who winters in a cellar to note carefully at what temperature his bees are quietest, and be governed accordingly. Is not a cellar with sub-ventilation warmer than one without? The air as it enters my cellar through the sub-ventilating-pipe has been no lower than 43° this winter, although the cellar has been as low as 36°, and outdoors 14° below zero. Later in the winter, the air from the pipe has, other winters, gone as low as 36°.

Since writing the above I have received GLEANINGS for Dec. 15, and read with very great interest the talks about temperature by Bro. Doolittle, Ernest, and yourself. Why should there not be a great difference in temperature between the north and south? After all, the practical questions come, What is the best temperature to keep a cellar? Should it gradually become warmer toward spring? What are the best means to secure the desired temperature? What is the best depth, all things considered, to run a ventilating-pipe? For, Bro. Root, although you prefer outdoor wintering, for many of us in other localities the cellar is the safer place, and answers to the above and kindred questions will be read by us with the keenest interest. If you will try your hand at it, and get others to do so, you will merit, and no doubt get, many thanks.

C. C. MILLER, 179—340.

Marengo, Ill., Dec. 21, 1885.

Friend M., we are very sorry to hear that you have had so poor a season; but before deciding that your locality is not a good one, I would consider the enormous yields you have made two or three seasons in succession, even though you had so large a number of bees in one locality. Would it not be better to take a little of the advice Doolittle gives in the present number, and get larger yields from fewer colonies, or else have them scattered more in different localities? The dwindling and swarming out in the spring seems to be a sort of mania, as we have many times mentioned, when things get to going wrong. We have had, in our locality, bees starve to death in June and July. After such experiences they seem to be always slow in building up.—In regard to my reply to friend Redd, I meant that during a warm night in the middle of the winter (such as we are having now this 24th day of December, and there has been no freezing night or day for three days, and one night was almost as warm as any night in June) the bees would sometimes raise the temperature of the cellar to 58 or 60°. I put this temperature from memory, as I don't know that I made a record; but had you been at the recent convention at Detroit you would have heard about cellars going up to even 90°, and that in Canada. To my great astonishment, the friend who gave this temperature is one of our most successful men in wintering his bees. When questioned, he admitted that the bees came out of their hives and clustered against and all over them, and all between them. But he said they went back all right when the temperature lowered. I have seen just such a state of affairs, but it resulted in the loss of several valuable queens. My experience in wintering in cellar, as a rule, gave about the temperature you mention. You have given us some very important facts in regard to sub-earth ventilation; namely, when the temperature is 14° below zero outside, your sub-earth tube delivered air in the cellar at a temperature not lower than 43°. I do not see why there should be a difference in the temperature of the earth north and south, if we get down deep enough to be beyond the influence of winter or summer—say eight feet deep, or may be a little more. And, by the way, friend M., will you please tell us how low down your sub-earth pipe is laid, and how large it is in diameter? In regard to the best temperature of a cellar, the different temperatures mentioned at the convention preferred by different individuals varied so greatly that it leaves one quite at sea. In the A B C book we have put it at 40°; but we mention there that some of the bee-keepers of York State prefer it as high as 50°. Now, very likely half way between the two, or 45°, will come as near it as we shall be able to agree on.

HOW TO USE THE SOLAR WAX-EXTRACTOR.

THE TEMPERATURE OF CALIFORNIA AS COMPARED WITH THE EASTERN STATES.

ON page 775, in a foot-note to my report you say, "I do not quite understand what you say about extracting honey as well as wax," referring to the solar wax-extractor. I have a case that will explain the operation very clearly. After we had done taking off our honey in August, I was requested by a friend who is in ill health to come down and take off his honey for him. He lives some fifteen miles nearer town than we do. Myself and nephew went down, never doubting but that we could take off the honey from the hundred hives, and house it, in one day. Imagine our consternation when we found there never had been any boxes put in the top stories, and that the bees had built just according to their "own sweet will." Well, we had to cut the honey out of the top stories of that whole hundred hives. We did that in two days, and stowed it away in barrels and five-gallon cans, in the honey-house. Now, you can't sell mass honey here at *any* price, so the only thing to be done was to get all this broken and mashed-up comb into extracted honey. I will here give you the *modus operandi*, remarking, by the way, that a great deal of the extracted honey produced in this county, and country too, is produced in just this way.

A SOLAR WAX-EXTRACTOR—HOW CONSTRUCTED.

A solar extractor is made exactly as you would make a trough out of two boards. This, you see, would produce two angles of reflection. But I made a half-octagon, so you see I have two angles of reflection *on each side*. Now you are ready for your tin lining. This must be all fitted neatly to the box, and well soldered together. Then put in your spout. If you intend to use this spout out of doors it must be of leather or rubber, so you can stick it into the honey-can and wrap a cloth around it, or you may get more bees than honey. Now make a light strong frame, to fit just half way down in your solar extractor. Cover it with wire cloth, well tacked on. Lay on this a piece of clean sacking, for a strainer. Now pile in your honey, keeping it as much in the middle as possible. The reason for this is, that you want the sides clear, to act as reflectors. Put on your sash and stop up your pipe. Of course, no bees must get into this honey, or they will never get out alive. The action of this sun extractor is thus:

The honey and comb both run through the cloth and wire screen into the lower part of the extractor. The honey sinks below, while the wax floats on top of it. The wax gets hard much sooner than the honey gets cold. You can therefore draw off the honey while it is warm, as it will run much easier and cleaner from the extractor. In the evening, when the bees are all in their "little beds," you can take off the sash and lift out the wax in great chunks that would "knock an ox down."

What do I melt small cakes of wax for? Well, I had that ton of honey at the end of the season, that the bees would not seal up. In each box of sections there would be one section at the end whose outside was not sealed up. It was unsalable. I therefore cut that cake out and left the box whole, so that it would pack right in the case. I made these cakes into extracted honey.

It is *not* a fact, that the heat of the sun is much greater here in our climate than it is in the States. In fact, it is not, to use a common saying, "half as hot." I have known *nights*, both in Pennsylvania and Ohio, that I think would have come pretty near to melting beeswax; nights when the denizens of great cities had to crowd out of doors to get even a breath of free air. The thermometer here generally ranges from 50 to 70° in the winter, and from 70 to 85° in the summer. It rarely gets up to 90°. *This* summer it was exceedingly hot — got to 90 several times. People thought they were burned up — entirely consumed. To-day I am melting beeswax, with the thermometer 70° in the shade. It is running in a swift stream about the thickness of a very thick darning-needle.

It is very singular to me that you can not melt beeswax there, with a temperature of from 85 to 105°, as you have it in the summer. Very singular, too, that you have to make shade for your hives, to keep the honey from melting down, and yet can not melt wax under glass, with a bright tin bottom and sides as reflectors. We don't have to shade our hives here. There is not one hive shaded in ten thousand, in this county. They are all ⅞ lumber at that. This speaks as loud as the thermometer, does it not? If you make your solar extractor right, and *can't* melt beeswax in it, it must be — climate. Ah! there we have got you. The only climate worth talking about is here. No other climate on the broad globe will melt beeswax with the thermometer at 70°. I am so glad! This—this is happiness.

——Italy,
With all her sunshine and her wealth of flowers,
Can never be thy equal. O'er her lowers
Malaria's gaunt and naked form. The sea
That sweeps her shores is not like this of ours.
She is not, then, thy peer, nor e'er can be,
O thou unclouded land along the sea!

J. P. ISRAEL.

San Dieguito, San Diego Co., Cal., Dec., 1885.

Friend Israel, I beg pardon, and own up, but some way I had got the idea into my head that your summers are much hotter than ours.—See what friend Poppleton has got to say about solar wax-extractors, on page 16. Truly there is a great deal to learn in regard to solar wax-extractors and some other things. That reminds me of what somebody said when Horace Greeley wrote his book, "What I Know about Farming." They said it would take a great deal larger book to hold what Horace Greeley did *not* know about farming.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

KANSAS CHIPS; KIND WORDS FOR GLEANINGS.

LAST spring I purchased three colonies of Italian bees (this being my first experience in the business); and during the spring and summer they were very "good natured," and we got along very pleasantly; but after the honey season commenced in July they became very cross, and, like Josh Billings' mule, "seemed to take especial pride in exhibiting the part where their strength lay." I suffered myself to be stung for awhile; but it finally got old, and I donned the veil and gloves, then I had them; and unless their disposition changes, or confidence in myself increases, I think I will keep on the safe side in the future. But I hope that, with Prof. Cook's Manual, and GLEANINGS, as counsel, and the veil and gloves for protection, I shall be able to succeed.

Apiculture is an experiment in this Western country at present; but I think, by raising sweet clover, alsike, and buckwheat, we may be able to make it profitable, to some extent at least.

I now have seven colonies—four new, and the three old ones. They are well stored for winter; but the new ones, being rather late, are not as strong as I should like.

I prize GLEANINGS very highly; and while I continue to try to handle bees I will be a subscriber; so that, when I say "stop," you may know that I am stung out of the business.

The supplies ordered of you all came in splendid condition, and gave perfect satisfaction. The foundation I thought very fine.

I am wintering in cellar. I did not get any honey this season, it being very wet here.

Jewell City, Kan. D. A. ATKINS.

A BEGINNER'S ENTHUSIASM; MOTHS; SCORCHED SORGHUM, ETC.

About nine years ago I paid five dollars for a large swarm of hybrids in an old American hive, with two or three frames of brood and honey, to start with. I also procured an old volume of King's text-book on bee-keeping, in connection with a few copies of King's periodicals. In perusing these books my enthusiasm for bee culture was aroused. It was here I first noticed A. I. Root's advertisement of GLEANINGS and supplies. His talk was quite homelike—so reliable, and not puffed up. The idea that he opposed patents—all things free—was so much to my taste that I at once sent for a sample of GLEANINGS. The sample came and I investigated until my enthusiasm caught to a flame. I was soon a subscriber to GLEANINGS, and really calculated the time that I should have 100 colonies, of thousands each, of living beings to gather in the luscious sweets of the country, and place it right at my feet. But, alas for a continued burning ambition without some realizations! I have barely succeeded in keeping the flame aglow. The burning is really painful at times. If apiculture is ever a success in these parts it will be of a cultivated source. Hitherto the profit (which consists mainly of "anticipation") does not cover expenses.

Last fall, a year ago, the "water" being dried up in my mouth for the taste of honey (hopes being blasted), I decided to try the queen business, and sent to friend Root for a choice imported Italian queen, which proved a "daisy" with me. Early last spring the yellow bands began to appear, and in a short time I had a full corps of Italian workers. Here my hopes took another "boom," as they seemed to work with more determination than I had been accustomed to see. In spite of the bad season last year, these bees did better, every way, than usual.

ITALIANS A SURE CURE FOR MOTHS.

Tell all who are troubled with moths, to Italianize. I firmly believe, if I were to place a frame, riddled with moths, in the midst of one of my hives, the bees would carry it out in less than two days.

SCORCHED SORGHUM.

Last fall I went into winter quarters with five stands, in good trim, as I thought. In the after part of the winter I noticed the bees of one hive coming out, at every warm spell, and perishing on the ground in every direction. By investigation I found solid sheets of sealed stuff which tasted like scorched sorghum. A part of the stores seemed to be grains of sugar, and some thick water mixed. When I overhauled the other four hives I found this watery substance would run out of the combs when tilted over. I threw a great deal of it out with my hands. A. P. STAIR.

Whitney, Ala.

RED ANTS KILLING QUEENS IN THE CELL; SIMPLICITY CHAFF HIVES.

My bees have acted very strangely indeed. One colony, consisting of a first and second after-swarm, cast a swarm; and no one being near, it flew away. When it was time for the young queens to hatch I examined the hive and found that the bees were tearing down the queen-cells, so I began examining those not torn open, and I found that, in every case, the immature queen was dead, and the cell infested with very small red ants, hardly visible to the naked eye. Do you think that the ants destroyed the queens, or did they get in after the queens died? I believe they killed the queens, else why should every cell be infested, and every queen dead? About a week afterward I gave the colony a hatching queen, and three days afterward there were eggs in all the combs but one.

On the 6th of Sept. an absconding swarm from a neighbor entered a hive containing a swarm. They killed my queen, and, having brought none with them, they had to wait until some of the cells (a number were already capped) should hatch. In the mean time I divided them. On the 13th the colony above mentioned cast a swarm, which I put in with a nucleus, but about half of the bees went back to the old hive. A day or two afterward another swarm issued and absconded. This all happened during a great dearth of honey.

Bees did very well on buckwheat, goldenrod, aster, ironweed, smartweed, and another weed that grows in damp places or on low lands, to the height of two or three feet, and has a bushy top, thickly set with small white blossoms. Stocks that had scarcely any honey have now enough for winter.

The select tested queen I bought of you is doing nicely; she has quite a large family of her own raising.

I have made a *simple* chaff hive as a kind of experiment. It is made just like a Simplicity, except that it is four inches longer, and the rear end is fastened in with three wood screws in each side, so as to be movable. When you wish to pack up your bees for winter, take out the screws, move the end-board back, and put in the screws. Slip in two 2-inch crosswise chaff cushions (made like your chaff-cushion division-boards), then a chaff cushion on each side; hang in your 7 frames of bees and stores; put on the winter covering, and, presto, you have a chaff hive all complete. What do you think of it? Has any one ever tried a hive of this description? If you think it worth naming, call it a "Simplicity chaff hive." **Alwin S. Heim.**

Chandler, Ind., Oct. 9, 1885.

For many years we have had reports in regard to red ants destroying queens; also in regard to their propensity to bite into queen-cells and destroy the inmates. We have learned some sad lessons in losing imported queens by leaving the cages containing them where the ants had access. You will find a foot-note referring to the matter, in the A B C book. I have known ants to do considerable damage where combs were left uncovered by the bees—especially combs containing queen-cells; but I do not know that we have had a report before where they invaded the hives. Very likely your hive was left comparatively unprotected, by casting a heavy swarm. In such a case I would try to find the nest of the red ants and treat them to boiling water or turpentine.—Simplicity hives made with a movable end-board have been suggested before. The objections are, that where you find it but little labor to fix over one hive, or, say, a small number of hives, with a large apiary you would find it, I think, altogether too much machinery. Another thing, such a hive is much more liable to be invaded by frost than the regular permanent chaff hive.

510 COLONIES IN WINTER QUARTERS.

I suppose you know we are in the bee-business pretty heavily, having gone into winter quarters with 510 colonies, kept in six different yards, or apiaries. We have a great many letters of inquiry about our management of bees in so many places, and why we don't write more for the papers, etc. Now, if you wish I will try to talk to the friends some this winter through Gleanings.

Plattevile, Wis. **Edwin France.**

To be sure, we know you are one of the big bee-keepers, friend F., and we are always glad to get reports from those who have such large experience as this number of colonies must give. Send us on your talks, and we will at least try to pay you for the time and trouble it takes.

CAN HONEY BE ADULTERATED WITH GRAPE SUGAR, AND NOT BE NOTICED?

I mail you a sample of honey (?). I bought it for white-clover honey, as advertised in Gleanings for September 15. It has occurred to me that something similar could be made of grape sugar and water with a greater or less proportion of honey; but I reserve judgment until I hear from you. What I wish to ask is, Would you be willing to sell this honey to your customers for pure honey? By giving your opinion you will greatly oblige.

Mt. Vernon, Iowa, Nov. 6, 1885. **Oliver Foster.**

Friend F., the sample of honey you send is about the nicest clover honey I ever tasted, and its being candied so perfectly white and solid is the best proof of its purity. The addition of even a very small quantity of grape sugar, by some means which I can not explain, *prevents* candying, instead of hastening it. Two or three years ago Prof. Cook made some careful experiments in this matter. The addition of grape sugar also gives the honey a peculiar flavor, which I think I should recognize readily. I am sure the honey from the friend you mention is absolutely pure; and, by the way, ought we not to be very careful about letting such ideas get into our heads? In regard to adulteration, if we as bee-keepers have not charity and faith in our fellow bee-keepers, how shall we expect the great world at large to hold fast to the beautiful thought contained in the sermon on charity—"thinketh no evil"? During the past year a great many samples have been sent to me, asking if I did not think such a sample was adulterated; but every single sample, so far, I have pronounced pure honey; and, what is still more strange, the most of the samples have been *extra* nice honey.

BEE-KEEPING IN THE REGION OF LAKE SUPERIOR.

As I think it probable that you never have had a correspondent from this region, and have probably no idea that bees can exist, or that they have ever had a chance to up here, I send you a few lines.

The bee business is in its infancy in this region of country; and whether it will ever get beyond that is generally conceded to be an uncertainty. I think that there are not more than fifteen hives of bees in the upper peninsula of Michigan. I have started in the business to make a success if I possibly can. I got two hives from Own Sound, Ont., last June. I have now four as the result. I have put my bees in the cellar, as our winters are more severe than yours, although a neighbor of ours is going to try his out of doors. What I fear the most is our late cool springs. Am I correct in thinking the snow ought to be mostly or all off in the spring before taking the bees out? **R. N. Adams.**

Sault de St. Marie, Mich., Nov. 19, 1885.

Friend A., as a rule the weather is hardly fit for bees to fly before the snow is all off, but circumstances may alter the case. We have occasionally a season when bees work quite industriously while considerable snow remains in the fields. Where there are high hills or mountains, the bees often work in valleys while snow covers the high lands.

SWEET CLOVER NOT YIELDING NECTAR.

My neighbor sowed about ½ acre in sweet clover last fall, and now it is in full bloom. He says there is not a bee at work on it yet, and it has been in bloom for 10 days. Can you tell us why they are not at work on it?

I commenced this spring with three colonies, Italians, and they have increased to 14, all in good condition now, and plenty of honey besides. I had 15 colonies of black bees in the spring, and they have increased to 28 colonies, and three of these colonies did not swarm at all, so I have about 42 colonies in all from 18 in the spring, and all natural swarms. I have no report yet on honey. **R. S. RAINS.**

Lovelady, Texas.

Friend R., we have had the same experience with sweet clover, but the next season it seemed to yield honey bountifully, and has every season since that. Sometimes the bees will not touch it while basswood or red clover is yielding, but they go on to it in great numbers as soon as the honey from these sources is gone.

THIN SECTIONS TO HOLD A POUND—HOW LARGE?

I want to make a section box 1 7-16 inches wide, of such size as to hold a pound. Can any of the readers of GLEANINGS give me the necessary information? How near will 4⅝ x 4⅝ x 1 7-16 be to the right size to hold 1 lb.? **W. S. VANDRUFF.**

Kirby, Pa., Nov. 19, 1885.

Friend V., it all depends on whether you expect to use separators or no separators. Without separators, I think the size you give would be pretty nearly right. If separators are used, you will want it, I should say at a rough guess, nearly 5 inches square; for 7-16 is no thicker than a good many brood-combs where honey is stored in the upper part.

A BEGINNER'S EXPERIENCE IN TRANSFERRING.

I must tell you about my progress at beeing. First my father kept bees for about 20 years, always afraid of them, and never took any honey, only "maby eight or nine pound" a year from seven or ten swarms; so I read A B C, bought a smoker from you, then I tackled the box hives and shook the bees in a Simplicity hive that I made. I took one hive of bees in the wood-shed, and was going to transfer (by book form), but I had trouble in getting the side off the hive until one bee took me "kazip" on the ear, then I settled to "biz." I got "astraddle" the hive, with hatchet and chisel in hands, and went to work. I got along finely, and kept on until I transferred ten hives (different days). I liked it, for it is so much fun; if I'd get stung 25 or 30 times, it soon would be forgotten while working with the bees. I had several swarms this summer, and several left. Honey was not very good for yield, but nice eating, although I got a fair supply—enough to sell some, and kept plenty to eat, which is about 150 to 300 lbs. for my brother and me. We are both small boys—about 180 lbs. apiece is our weight, and we like honey. I tried to get my brother to eat too much honey, so he would get sick, and I could try the remedy for colic—that is, only plenty of sweet milk, and drink it; but he was not subject to any such ailings. I had some sections partly filled, so I took all out except one hive, and in front of that I put a box filled with these partly filled sections, for the bees to take up the honey from below and finish filling their partly filled ones; so I completed some sections, and the rest are empty, ready for next year. I noticed last spring with my bees that I could tell (by smelling) the difference between drone and worker comb. Is it a common thing? Can bees hear any sound that is loud, such as loud talking?

Aviston, Ill. **J. J. RANDALL.**

Friend R., your plan for getting the bees to complete partly filled sections, I should think, would be in great danger of inciting robbing. However, if you have got along all right, that is all that is wanted.—I have never before heard of anybody who could tell drone from worker comb by the smell. We should be glad to have others try it and report.—The matter in regard to bees hearing has been pretty fully discussed in our back volumes. The general decision seemed to be that they could not hear unless the sound were accompanied by some sort of a jar; but as more or less jar accompanies every sound that is made, I do not see how the question can be very definitely answered.

QUESTIONS FROM A BEGINNER IN REGARD TO WINTERING.

I do not like to bother you very much; but if you will answer two or three questions I shall be obliged. I have got my bees all in two-story chaff hives, with oat-chaff cushions on top, and three one-inch pieces under the cushion to hold it up. The cushion fits in pretty close, but the frost comes up around it. Do you think it will do any harm? They have got all of their frames of honey, nine and ten, the same as they had all summer. We have lots of snow here now. The wind blew so the other night that it filled the entrances full of snow, and it froze in there so full that no air can get out. Is it safe to leave it in there, or would you dig it out? I tried to dig out some of it, and the bees came out on the snow and died. I have a swarm of bees that are very sick now. They are crawling out and dying all the time. The queen is a daughter of the imported queen I got of you. As it is a good colony I do not like to lose it. If you can tell me any thing about it I shall be very glad. **FRANCIS C. SMITH.**

Kilmanaugh, Mich., Dec. 7, 1885.

I do not think the frost is any thing out of the way, friend S. The moisture from the breath of the bees ought to come up around the cushion; and where the weather is very severe, of course it will make frost around the openings. Don't bother with the snow at all. I can not remember where I have ever known snow to do harm. On the contrary, it is the bee-keeper's best friend; and yet we have more inquiries every winter in regard to snow around the entrances than almost any other one subject. Disturbing the bees by trying to clear the entrances results just about as you mention. I do not know what is the trouble with your sick bees, unless it is that they have bad honey. Putting lumps of candy right over the bees, so that they may subsist on candy stores instead of the honey in the combs, will sometimes stop the trouble until we have weather warm enough to permit them to fly out.

WASTE MICA FOR BEE-VEIL FRONTS.

I notice, in June GLEANINGS, your remarks about bee-veils having glass fronts. Now, there are several objections to glass, which are too obvious to mention. I sent for some samples of waste mica from the works here, where it is mined and cut for use in stoves. Would not this material be excellent for the bee-veils? It will not break, and can be perforated with a needle, and sown on to the netting. It is also cheaper than glass, as it can be got here for a dollar a pound, and a pound would have several hundred pieces in it. You will notice how easily it can be split to any thinness, and can be cut with scissors. If you would like some of it to test I shall be glad to send you some. H. STEWART.

Webster, N. C.

Thanks, friend S.; but mica has already been used for the purpose you mention. A few years ago it was advertised in GLEANINGS, and tested considerably; but although it does not break like glass, it has the same objection of being made obscure by dampness from the breath, and by getting soiled and dusty, so it must be wiped almost every time a veil is used. On these accounts it has been dropped. Thanks for the beautiful specimens you send.

AN APOLOGY TO MRS. COTTON.

I send you a letter, received from Mrs. Cotton, asking me if I authorized you to publish her as a humbug. Now, friend Root, I think that I owe Mrs. Cotton an apology. At the close of our correspondence in regard to that colony of bees, Mrs. C. made a proposition that she would send me another colony in the spring. I wrote her that I was perfectly satisfied, and I have now no reason to doubt that she will do just as she agreed to. Therefore I had no reason to write what I did, and I feel that I did Mrs. C. a great injury, and I am willing to acknowledge it. H. ADAMS.

Port Austin, Mich., Dec. 14, 1885.

We are glad indeed to hear so much in Mrs. Cotton's favor; and I agree with you, friend A., that it is a manly thing to do, to make acknowledgment when we fear we have been unwise.

HOW I RAISED SOME MOTH.

Now for the moth. I took two nice frames of comb, one containing 2 or 3 lbs. of honey capped over, and I put some sugar syrup into the other card. I have had these right in the house where I live for nearly two months. There was no sign of moth or worms in either card of comb when I brought them in, and the other day I took out the card that I had put the syrup in, and it was destroyed by the moth. Some of the worms were over one inch in length, while others were half grown, and still others not over one-fourth of an inch long. Now, how is this? I thought that a gray miller laid the eggs that produced these worms. Had these eggs all been laid while the comb was in the hive, why did they not all hatch at once, and the worms all be of one size? or do the worms produce eggs? which will you have it? There could possibly no miller get at these two cards, for I had them in a close-fitting box, with fine wire over the entrance.

Mineral Point, Mo., Dec. 16, 1885. O. F. BEAL.

Friend B., it is well established that moth is almost sure to hatch out from brood-combs when removed from the hives during warm weather. You will find the same thing mentioned in the A B C book. Without question, the combs contained eggs that remained in a dormant state until the warm temperature of the house caused them to hatch. I believe it is pretty well decided, however, that the worms do but little harm unless the combs contain pollen. With plenty of pollen for them to feed on, there is no trouble in getting moth worms an inch long, or even longer. I do not know how long the eggs will remain in the combs without hatching, but perhaps a year or more, if the temperature is not warm enough for them to hatch, nor cold enough to kill the eggs; for the eggs are not always killed unless they are subjected to a freezing as severe as 15 or 20 above zero.

FRIEND GOULD INTRODUCES HIMSELF TO OUR READERS IN POETIC MEASURE.

Good morning, Messrs. bee-men, and bee-women too,
For I'm bound to be a bee-man, what else I may do.
On the sea of bee-fame I've launched my canoe,
So here is my ☞ with a "how do you do?"
As an A B C scholar, about the first of June
I commenced handling bees, and getting used to their tune.
Twelve four-frame nuclei and two full stocks
Was the shape of my lesson, and size of my flock.
Seven divides and fifteen introductions I've successfully done,
Including four queenless colonies, with fertile worker one.
Made twenty-four hives of Simplicity style,
With inside fixin's, but haven't struck ile.
The gathering, in this section, has been so slim
That the bees havn't brought in the sweets with a vim,
So that, instead of BIG yields, which so many boast,
I've hardly enough to spread on my toast.
But where there is life, they say " there is hope,"
So, if my bees live, I will " give them more rope,"
As I've twelve Simplicities buried in a hill,
And thirteen on summer stands—they can't freeze if they will.
While two swarms took wing and got out of my range,
Counting one, which I sold, and you can see the increase,
Allowing two, which I doubled, to save me their fleece.
Of foundation, I've used thirty pounds or less,
Which has initiated me in most of the manipulations, I guess.
I've done all this work unaided and alone,
Without having once been stung—by a drone.
So, whether I'm well up in my class, or to be placed at the foot,
I leave the decision to—A. I. Root.

Corunna, Mich. J. T. GOULD.

A PLEA FOR THE MUCH-ABUSED MILKWEED.

I inclose a slip cut from the *Planter and Stockman*, of St. Louis. Either the editor must be mistaken, or the milkweed acts differently in different localities; for I can truly say, that if it had not been for milkweed the writer would have been in Blasted Hopes long ago, for three-fourths of our honey crop is from that same milkweed. Though I have diligently searched for bees that were so loaded down as to be unable to leave the blossom at all, I have not yet found any. I know that the bees go in at the entrance, and out of sight, with milkweed honey, but I do not know that they climb the combs; but I *do* know that the honey gets into the section boxes in very nice shape. I never yet saw any fighting when milkweed was in bloom, but I have seen quite a little pile of the balls that stick to their feet on the ground in front of the hive, sometimes as much as a small handful. I often see bees come out of the hive fastened together with it, and fly away after more stores, sometimes separating on the bottom-board, and sometimes after flying a few feet, and sometimes going out of sight together. Long live the milkweed!

GEO. L. HUBBARD.

Fairview, Dak., Dec. 26, 1885.

Friend H., I have long suspected that the damage done the bees by the milkweed was somewhat exaggerated, therefore I am very glad to have you give us positive facts in regard to the matter. From your statement I should infer that your bees were troubled about as much as bees ever are with these impediments on their feet.

REPORT FROM THE REVERSING DEVICES, ETC.

Thanks for the bellows spring. It came just in time for use; it works admirably. I will see that you lose nothing. I shall need some more reversers in the spring. I couldn't make the bees take the honey out and store it in the sections. I would break their cappings, but they would repair them and seal them up. But they are very handy to have, and I prefer them to the tins. If any one has been successful in getting the honey taken out and stored above, I should like to see a report, in GLEANINGS, of the manner and mode of operation generally.

ASTONISHING THE "OLD WISDOMS."

I had six colonies in the spring, all in good shape. One lost the queen early in April, and didn't do very much till I put on a new queen. I had no increase, and took out 359 full sections of white-clover and basswood honey, and have from 50 to 75 lbs. in partly filled sections. I took 94 full sections from one young swarm, and there is fully 15 lbs. left in partly filled sections. This large result astounds the "old wisdoms," who still put their trust in box hives and nail-kegs, and now they are "goin' to git" some of

"THESE 'ERE NEW FIXIN'S."

I prevented increase by following the directions of Prof. Cook, by hiving No. 2 where No. 1 went out. There was a great yield in basswood, but the buckwheat yield was almost nothing, though there was 100 acres within a radius of two miles. With us, buckwheat usually gives a large yield; but it was wet and cold this year, just when the buckwheat blossomed. I raise honey for my own amusement generally, and to give to my friends; but I like to make a success of it. A. POTTER.

Bennington, Vt., Sept. 30, 1885.

A POOR SEASON.

Our bees are laid up for their winter repose. We have no large reports to make, but still the ball is rolling. This has been one of the poorest years known for fifteen years. We have been using the Heddon cover, but do not like them, for the bees build ladders of wax to them; and when the covers are raised it pulls the frames with them, killing a number of bees. One desirable point is their cheapness. "Where there is a will there's a way," is an old saying, but a good one. We are not in Blasted Hopes, but our bees have gathered but little honey —about 300 lbs. in all, or not enough to supply our home market. We have been helping some of the brethren out of the fire by selling their honey. We also have to show for our work a fine lot of home-bred Italians. W. S. DORNAN.

Mechanicsville, Ia., Dec. 5, 1885.

EIGHT SWARMS LOST BY COWS KNOCKING THEM OVER.

As I am a beginner in bee culture, I do not know that my report will be of any advantage to the science of bee culture. This is my third year in the business. The winter of 1884 I carelessly lost eight colonies out of 16 by my cow getting to my hives one night when it was raining hard, and knocking the tops off to get the leaves they were filled with; so this past winter I concluded to remedy that trouble by covering with old carpet, setting my stand on the ground with only inch pieces under them. I then put boards to the sides and back, as high as the first story, and banked with dirt; and as we had an unusual amount of snow, my bees were covered with nearly 18 inches of snow and two heavy crusts, so I know they did not freeze. I had 19 stands to start with, but three of them I knew could not get through without being fed through the winter; but when winter once set in, the feeding played out, so they "went."

INTERFERING WITH THE LOWER STORY.

That hive I bought of you I filled with a swarm. They filled the lower story full, and then 28 1-lb. boxes on top. Had I taken the top crate off, and let the lower story alone, I am sure they would have gone through all right; but I took out the 16 pound boxes from below, when they could make no more honey; consequently they starved. So I have learned that it will not do to risk interfering with the lower stores in this country.

SMOTHERING BEES WITH ICE AND SLEET.

Last winter I had two stands I think smothered, as the whole hive was hermetically sealed under two crusts of ice, and at one time the sleet sealed the entrance for a few days before I discovered their condition; and when I opened them this spring the covers were as wet as water. They had 15 or 20 lbs. of honey apiece left. I have about 3 hives, where I ought to turn in, on the racks of comb, a pound of bees and a queen, but I know of no bee-man handy for me to get them.

Daleville, Ind. W. W. CORNELIUS.

Friend C., had your hives been made properly, I do not think your bees could have smothered, even under two crusts of ice, as you mention. What I mean by "properly made" is, with ventilators under the cover that can not be stopped with ice and snow, and a porous covering over the brood-nest.

A GOOD WORD FOR GEO. E. HILTON'S CHAFF HIVES.

I have noticed the cut of friend Hilton's hive and apiary, with a great deal of admiration. I have used this hive for the past three years by the side of others; and for a hive to produce comb or extracted honey, as a non-swarming and wintering hive, I feel it would be hard to excel. The large capacity for storing surplus in crates or super he uses, gives them so much room at the right time, and the advantage of replacing empty sections has a tendency to retard if not prevent swarming. The heavy walls and winter cushions with large air-space above make them an excellent wintering hive. I now have 57 of those hives in my apiary, painted in six colors, which renders them very attractive. In this part of the country, where losses by wintering are quite heavy, I can especially recommend them.

TROUT CULTURE.

I notice, also, you are interested in fish culture. Well, I raise speckled trout, the common brook trout. I now have specimens which will weigh 2½ pounds—little beauties. I am hatching 40,000 this winter. My ponds are not completed, which will be seven in number. The work, however, is being rapidly pushed by the contractor. They are costing $1200, and it remains a conundrum whether I ever get back my money. The trout is not as easily raised as the carp. They require cold water; they can not live in water above 70°. The price of trout is usually 50 cts. per lb. here, and often more. Perhaps I may write you again upon my success or failure. W. D. FRENCH.

Grand Rapids, Mich., Nov. 16, 1885.

Friend F., I am very glad indeed to know that speckled trout can be propagated in the way you mention. Has the matter ever been made a success? At half the price you mention, it seems to me it would be a wonderful achievement, and speckled trout would sell in our city markets at good prices in immense quantities, without doubt. By all means tell us how your experiment turns out. It seems to me you are starting in pretty heavily, if it is indeed an entirely new industry.

THAT NAMELESS BEE-DISEASE.

I had some questions to ask, concerning one swarm, but I see you have satisfied me in a late issue of GLEANINGS, except dates. Yours is August 28, mine is July 3. One queen, with 1 lb. of bees, bought July 3, has all the symptoms named in that piece, that unknown bee-disease, and it is fast dwindling away. I don't think there are bees enough left to make one pound. They have been thinning their ranks for six weeks. I have been watching them very closely, and never, in all my experience in 25 years, have I seen any thing like it. It produces such odd-looking, mangled bees. Some look like beetles and flies, small head and neck, and shoulders large; black and shiny abdomen.

Spencer, Ohio. **WM. DAGUE, SR.**

REPORTS ENCOURAGING.

FROM 29 TO 51, AND 3100 LBS. OF HONEY.

MY report for 1885. I went into winter quarters in the fall of 1884 with 47 colonies, and came through with 31—three-fourths of them very weak. I sold two, leaving 29 to commence the season with. I increased to 51 and got 3100 lbs. of surplus honey, extracted, except 150 lbs. comb honey. Nearly all is sold at 10 and 12½ cts. per pound for extracted and 15 to 20 cts. for comb. Bees have plenty of honey of a good quality for winter supplies. **L. G. PURVIS.**

Forest City, Mo.

FROM 15 TO 48, AND 2500 LBS. HONEY.

This is the way our bees panned out this year. Spring count, 15 colonies. Increased to 48, and took 2500 lbs. surplus honey—1800 comb, and 700 extracted, worth on an average 15 cents per lb. Increase of bees, 33 colonies, at $5.00 per colony, $165.00; 2500 lbs. honey at 15 cents, $375.00; total, $540.00, or $36.00 per colony. I attribute much of this success to sweet clover. **E. W. PITZER.**

Hillsdale, Iowa, Dec. 25, 1885.

FROM 84 TO 129, AND 9000 POUNDS OF HONEY.

I commenced the season with 84 colonies, all blacks but 6. I increased to 129, and took 9000 lbs. of honey. I have about 120 hybrids and Italians now. The black bees did no good this season. The spring honey crop was a failure, but we had a honey-flow in the summer and fall. I am very well satisfied with the season's work, but count it about half a crop. 3—**D. M. EDWARDS**, 84—129.

Uvalde, Tex., Dec. 2, 1885.

FROM 18 TO 51, AND 1000 LBS. OF HONEY.

Our bees were reduced to 18 swarms last spring, and nine were weak. We increased to 51 good colonies, with abundance of natural stores for winter, and have taken about 1000 lbs. of honey, mostly extracted, clover and basswood, and some fall honey. I like the Syrio-Italians, large red clover (pastured for seed it has smaller heads than the small red clover), and the Langstroth chaff hive. Our spring dwindling was mostly of those wintered in the cellar. **ILA MICHENER.**

Low Banks, Ont., Dec. 4, 1885.

5000 LBS. OF COMB HONEY FROM BASSWOOD.

With the aid of very fine weather I have secured about 5000 lbs. of basswood honey in sections—a very light crop, though it is one of the poorest seasons we have had for years. Our basswood began to bloom on June 14, and I saw this day on the highest ridges trees which had not bloomed, and they were full of young buds. **A. W. CHENEY.**

Kanawha Falls, W. Va., July 10, 1885.

FROM 83 TO 160, AND 3500 LBS. OF HONEY.

I started this season with 83 colonies of pure and hybrid Italians; increased by natural swarming to 160 colonies (did not accept any after-swarms). Amount of surplus, 2300 lbs. of white-clover honey in 1¼-lb. sections, and 1200 lbs. extracted. This was a poor season, too wet and cold. I have now 140 colonies all ready for cellar, but we are having very mild weather. Last year bees were taken into cellar Nov. 20, and wintered very well. **W. ADDENBROOKE.**

North Prairie, Wis., Dec. 4, 1885.

A GOOD REPORT FROM VERMONT.

I commenced bee-keeping in the fall of 1884, by buying two swarms of black bees in Langstroth hives. One died out in the winter. The other came out all right; swarmed once, and made 68 lbs. of surplus. The new swarm made 20 lbs. of surplus, besides enough to winter on. They had only one frame of comb, no fdn. I bought five swarms of Italians this fall at $6.00 a swarm. If they live this winter, I shall get foundation another spring. There are acres of raspberries about here.

Barre, Vt., Nov. 23, 1885. **H. W. SCOTT.**

FROM 10 TO 20, AND 400 LBS. OF HONEY.

Here is my report for 1885: I purchased this spring ten colonies in movable-frame hives, paying $45.00 for the ten. The hives were not the same size as the one I use, so I transferred most of them to the standard Langstroth hive. These bees were mostly hybrids, with one pure Italian and one black stock; every original stand cast one swarm, but I did not allow them to cast any more than one. The Italian stock was the first one to swarm; and from this swarm and the parent stock I got over 100 lbs. of comb honey. My total yield was 300 lbs. comb and 100 extracted, and increased from 10 to 20, good strong colonies. I introduced five of A. I. Root's dollar queens, of which I lost two in introducing. I took a case of comb honey and a few jars of extracted to our county fair, and was awarded first premium on comb and second on extracted. The premiums amounted to six dollars, which was quite a help to one just starting in the business. This has been a very poor honey season in this county. Bee-keepers who had a large number of stands did not get any surplus, so I am well satisfied with my gains, and am thankful. **HARRY LATHROP.**

Browntown, Wis.

128 LBS. OF BUCKWHEAT FROM ONE POUND.

I bought one pound of silverhull buckwheat of you last spring, and I thrashed 128 lbs. from that one pound. My bees went into winter quarters in good condition, and with plenty of stores.

Blairtown, Iowa. **O. P. NICHOLS.**

I should think the above was a very extraordinary yield, friend N. It is worth something, any way, to know the capabilities of silverhull buckwheat. We presume you gave it every advantage of soil and cultivation.

SHORT REPORT FROM FRIEND HART.

ROBBING IN FLORIDA.

MR. HARRY MITCHELL, who has been with me for the past four years, and had full control of my bees for the past two, has now left me, and gone to his own place, half a mile away. When he went away I sold him twenty-five colonies of bees to start an apiary of his own with, and it's my opinion that those twenty-five colonies will never disgrace the apiarian interests of this State while under Harry's charge. This sale leaves me with 125 colonies to start with next season, "if I carry them through the winter," a Northerner might say; but that is hardly necessary here, as I can work with them almost any day, and can commence to raise queens in February, if need be. I have just finished looking them all over, having been at work on them the past four days, Sunday excepted, and I find them in prime condition. There are five out of the lot that were sufficiently short of bees so that I thought best to take off the top sections, to economize heat. I also have two very small colonies in one-story hives, made a few weeks ago by uniting four small nuclei, two nuclei to the colony. These seven are in good shape, although small in numbers, and will no doubt be strong colonies early in March. The rest are in two and three story hives, and are as strong in bees as I have ever known them to be at this time of year. I believe that they will average from 30 to 40 pounds of honey each, and some three-story hives have at least 50 pounds each.

It has been my custom, at the close of the main honey-flow, early in August, to leave twenty pounds of honey in each hive, and I think Harry has done the same. If so, the bees have done quite well during the fall from small wild flowers. Mr. O. O. Poppleton, from Iowa, who is now stopping on his property here, and Mr. Storer, from Nebraska, were both with me for a while this afternoon, and both pronounced my bees to be in fine condition. They seemed surprised at my being able to open hive after hive, and handle the combs freely, many of them containing considerable new uncapped honey and pollen, and yet not start robbing. Many Northerners have an idea that bees in this State are always ready to start a robbing spree on the least encouragement, and some of the bee-men near here declare that this is the case; but I believe that their trouble comes from educating their bees to it. It is true, that robbers here, as anywhere else, have to be guarded against for a while after a honey-flow ceases; but my experience has never shown any greater tendency in my bees toward that direction here than I am led to believe exists elsewhere, although they have much more time during each year in which to develop the trait. I have never seen a case of robbing here among the bees that could not be quickly stopped by placing wet cloths at the hive-entrances, so that all bees going in or out had to pass over and under them. To hasten matters it is well to sprinkle those that are flying about, with water from a fountain pump. The wet hay used by some bee-keepers answers the same purpose.

While at work in the apiary to-day I have noticed quite a number of wasps, or yellow-jackets, as they are called, tearing the abdomen of the bees from the thorax so that they could get at the honey-sack and its contents. If I ever noticed any thing of the kind before, I have forgotten it. A small swarm came to me day before yesterday which I hived on six frames. The queen is now laying, and evidently intends to remain and raise a family. I am liable to come out at the beginning of next season with more than I had at the close of last season, as this is the second swarm to come this winter. My oranges are cracking quite badly on the trees this year; and the bees, knowing a good thing when they see it, are helping themselves to the juice.

9—W. S. Hart, 125.

Hawk's Park, Fla., Dec. 21, 1885.

Friend H., I quite agree with you that this whole matter of robbing depends upon the management. During the past season, although we have had between 300 and 400 colonies at one time, and many of them quite weak, comparatively, for they are used for queen-rearing, yet we had scarcely a case of robbing. The bees didn't get once started, and therefore it was but little work to keep them from it. Attending to little things at just the right time is the great secret of avoiding such disasters. I have sometimes, in utter discouragement, almost concluded there were certain people who could never learn to be successful with bees, just because no amount of exhortation or entreaty, and, in fact, no amount of disasters and heavy losses, could teach them by experience the importance of keeping every drop of honey, or any other kind of sweet, so carefully out of the way that not one bee ever got one load, and got home with it. The same rule applies to bees troubling candy-shops on the fair-grounds. Tell the proprietor to kill the first bee that commences to load up on his lemonade or pop-corn balls; and if he will do as you direct, a very little time will make him master of the situation.

HUMBUGS AND SWINDLES.

MORE ABOUT HULLESS OATS.

THERE are men going around here selling Bohemian oats at five dollars a bushel, and agree to give one dollar a bushel for all the farmers can raise from this seed. There is a "Bohemian Oats" association some place in Ohio; do you know where it is? I did not take any myself, but five of my neighbors are in for fifty dollars apiece.

Hiram Weaver.

Scircleville, Clinton Co., Ind., Nov. 7, 1885.

Friend W., the swindles of the Bohemian-oat men are now so thoroughly published in almost all our agricultural papers that it seems to me strange that a man can be found anywhere who is not well enough posted to turn a cold shoulder to them at once. A good many associations have been formed in our State; and although a few men may have got some money out of it, they have got a bad name that will last them to the end of their lives, unless they repent and restore the money to its rightful owners.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, JAN. 1, 1886.

He that is greatest among you, let him be as the younger; and he that is chief, as he that doth serve.—LUKE 22: 26.

DISCOUNTS FOR THE MONTH OF JANUARY, 1886.

As business is still moderate, a discount of 4 per cent on all orders sent us during this month will be allowed.

The discount of 10 per cent on foundation will be continued so long as the price of wax remains where it is.

THE KANSAS BEE-KEEPER.

IN response to the editorial in our issue for Nov. 1, friend Scovill replies as follows in regard to the unexpired time on his subscription-list:

> I am now paying back amounts due, as fast as I can, and shall continue till all are paid. H. SCOVILL.
> Galena, Kan., Dec. 2, 1885.

AN OMISSION.

MY attention is called to the fact that I omitted to say that the beautiful volume of Paradise Lost was presented to me as a birthday present. Remember, I told you, in an editorial in our issue of Dec. 1, that I should be 46 years old on the second day of the convention.

FATHER LANGSTROTH'S BOOK UNDERGOING REVISION.

I AM pleased to make the above announcement, and also to be able to tell the bee-friends that the work is in the hands of such able men as Charles Dadant & Son. I can not say just how soon it will be out—may be some little time yet; but when it comes it will be fully abreast of the times.

NUMBER OF SUBSCRIBERS TO GLEANINGS ON THE LAST DAY OF 1885.

ALTHOUGH we have not as many as we had one year ago to-day, friends, I am happy to find that, by actual count, we have 4045 to start the year with. Considering the general depression in business, losses during the winter of a year ago, and the low prices in almost every thing, we think we have abundant reason to say, "Thank you."

FRIEND HEDDON ALSO AT WORK ON A BEE-BOOK.

WE are also pleased to note that friend Heddon is hard at work embodying the many good things he has given us in years past, in a book on bee culture. No matter how many bee-books you have already, I presume every one will want to add Heddon's book to his collection. We do not know when it will make its appearance, but we presume friend Heddon means to take time enough to do it well while he is about it.

BOUND VOLUMES OF GLEANINGS FOR 1885.

As we have quite a good many left over, we will furnish these, neatly bound in cloth, for an even $1.00, and pay postage besides. If you want a bound volume by express or freight, with other goods, the price will be 80 cents. If any one should want to know what we will charge to swap one of these bound volumes for your old ones unbound, the price will be 40 cts., you paying all postage both ways.

THE BRITISH BEE JOURNAL A WEEKLY.

WE have now three weekly bee-journals well established—the *A. B. J.*, the *B. B. J.*, and the *C. B. J.* The *B. B. J.* commences as a weekly during this present year, 1886. We have not completed arrangements yet with the publishers for our usual exchange; but until further notice we will furnish it with GLEANINGS for $3.50 per year. Since it is weekly, the postage amounts to something like 50 cts. a year.

CHARLES F. MUTH & SON.

WE are infomed by postal card that hereafter the above will be the name of the firm that does business in place of the usual C. F. Muth. And that is the way to do it. When we old folks get well along in life, let us allow some of these responsibilities to rest on the shoulders of the younger ones, while we attend conventions, make neighborly visits, and stir around enough to knock off the sharp corners. Best wishes to the new firm.

REPORT OF THE N. A. B. K. A. AT DETROIT.

As both the *American Bee Journal* and *Canadian Bee Journal* have given such very full and excellent reports of the proceedings of this convention, it hardly seems to me to be worth while for GLEANINGS to go over the same ground again. So many of our bee-keepers have the journals, it seems hardly advisable to have the same matter in all of them, especially while there is such a great amount of good original matter before us. If you do not take either of the above journals you can get, for only a few cents, copies containing these reports. I shall refer to the points considered there as they come up occasionally in our discussions, perhaps for a year to come. The report will occupy 62 columns of the *American Bee Journal.*

KIND WORDS FROM OUR CUSTOMERS.

The imported queen and bees came all right. I introduced her to a frame of brood last evening. They are all right this morning. I am well pleased with her. J. E. WINDLE.
Lafayette, Ind., Sept. 23.

BECOMING A CHRISTIAN CHANGES ONE'S VIEWS.

Having had some deal with you, I take the privilege to write you. I want to say a word in regard to mixing up subjects in GLEANINGS. I will say, I like to have it mixed with different subjects. Before I was a subscriber I would borrow GLEANINGS of a friend of mine, and I was one of those fault finding ones; and when I received your A B C book I found more fault than ever, because there was so much "religion" in it, as I called it. But about one year ago I gave my heart to God. Though it was dark at first, those clouds have all passed away, and GLEANINGS has been a great help to me. Those Home readings are good. I love to have the subject of religion mixed up with all of my doings, and put on the whole armor of God.

I have kept bees for seven years, and have not had very good luck until the last year, when they did well for increase, but not much honey. But I have learned to love God and all his creatures. My home is happier, which accounts for my bees doing better, and I am happier, all because we are trying to follow the path our Savior has laid out for us.

I have 17 swarms of bees. The most of them are in chaff hives, very strong, part Italians and part blacks. IRA D. GRANGER.
Madison, O., Nov. 16, 1885.

TELEPHONE.

The little telephone does the work. J. B. COOL.
Red River, Darke Co., O.

Poultry netting arrived on the 8th all O. K. Thanks for promptness. J. M. HYNE.
Stewartsville, Ind., Dec. 11, 1885.

OUR EXTRACTORS.

The honey-extractor I bought of you works to a charm. I am well pleased with it. It is well worth the money. I took 30 lbs. of honey in 6 days from one colony of Italians. C. D. FARNHAM.
Fleetville, Pa.

I am well pleased with the extractor you sent me last week. It does its work up to the handle, and the knife gives good satisfaction. It came to hand in good trim. W. F. MATZDORFF.
Goshen, Ind.

HOW IT PAYS TO ADVERTISE IN GLEANINGS.

By advertising in GLEANINGS my honey is all sold; and as I am still getting orders, please tell the public my honey is all sold. J. B. MURRAY.
Ada, O., Dec. 5, 1885.

Please find small advertisement inclosed. By advertising last fall you sold for me 329 colonies of bees, and I hope your printer's ink will do as well for me this winter and spring. ANTHONY OPP.
Helena, Ark., Oct. 29, 1885.

The A B C of Bee Culture came to me yesterday in good shape and condition. Many thanks for your very prompt attention and kindness. You shall hear from me again oftener in the future.
Dayton, O., Dec. 12, 1885. LEO P. DHEIN.

NEVER STOP GLEANINGS.

Inclosed find one dollar. Stop GLEANINGS? Never! Too many good things in it for one dollar, so send it along. WM. BATTLES.
Blairsville, Pa.

GROWLERY NO MORE.

Goods received in good shape. No wonder the Growlery has died out in GLEANINGS. Many thanks. The order was filled perfectly, though it was so badly mixed. A. L. LIGHT.
Pastoria, Ark.

The advance in apiculture knows no bounds. The ice chains, wrought by November storms, did not prevent the safe arrival of the tested queen sent by you Nov. 23d. Bees and queen were as lively as though there were no snow. J. F. MICHAEL.
German, O., Nov. 25, 1885.

The queen was received in good order, and is better marked than one I have seen which was *very* black. Thanks. I shall cross some of her drones next season on some of my Syrio-albino queens, and see the result. I think she is safely introduced.
New Philadelphia, O., Oct. 22. G. L. TINKER.

20-CENT SHEARS.

I sent to you last fall and got a pair of your 20-cent shears, and I must say that I was surprised, when I untied the package, to find such a nice pair for so small a sum of money. They are as good as we could find at any price, as far as I can see, and they cut nicely. I want 7 more pair just like them, to supply my neighbors. ADELBERT COOK.
Norwich, N. Y.

The three tested queens I bought of you in May did well; also the other queens — that is, the $1.25 queens. I bought three of you, but I did not get the queen-cage fastened rightly on the comb of one of them, and she got out too soon; and during the same night some time, the bees killed her; but I have two skeps from the other two queens that are the nicest-marked Italians I ever saw, and fine workers. They are now, I think, my last queens.
Loudonville, O. J. F. REED.

While I have been away from home nearly all summer, in the discharge of official duties, and have seen but little of GLEANINGS, I have lost none of my love for the business, and hope I may now have time in the coming months to read all you may have to say, for I have become interested in what you say *outside* of the question of bees and honey. Although you are peculiar, I can't help admiring your very frank, honest, and earnest ways. I intend sending for your book on carp culture. ED. R. ALLEN.
Kansas City, Mo., Oct. 19, 1885.

OUR CARLOAD OF CALIFORNIA HONEY; MELTING CLOVER HONEY, ETC.

My order for honey has brought it in good time, and with very reasonable freight charges. It was received in best condition on the 18th, and the California honey is simply magnificent. I wish my order for it had been much larger. The clover is candied, and stays white and slushy, even when put into hot water. Can it be perfectly thawed and cleared? F. M. POTTS.
Media, Pa., Dec. 24, 1885.

[Friend P., your clover honey has not been warmed enough, or you have not waited long enough. It will surely become perfectly clear and transparent, when melted, as you have probably found out by this time.]

KIND WORDS FROM THE AUTHOR OF "THE STORY OF THE BIBLE."

[After the very favorable notice I gave "Fables and Allegories" was submitted to the author I received from him the following kind letter, which he doubtless did not intend for publication; but I want to give it to you, as it illustrates so fully the point that there is no great excellence without great labor. Friend Foster tells us of the long, faithful, and earnest work required to get up such a book, and the world is just beginning to appreciate it.]

My Dear Sir:

Anybody who undertakes to get up a book full of *new* pictures, 350 of them, to have them drawn first, then engraved, then printed (not to speak of the money laid out), finds he has big job on hand, and it is a long one. Good things can't be done in a day. Your good artist wants time, so does your engraver, and so does your printer. But there is such a thing as fighting through it, and getting it all done, and done handsomely. Well, then to have it appreciated does come good. There is something about that, that pays a man (in a certain sense) better than the money profit. Now, my friend, I want to thank you for the appreciation you have shown of the pictures in the "Fables," by your advertisement. Numbers of pleasant things have been said, but I don't remember that a single customer has seemed to *feel* the beauty of the "get-up" of that book as you have. I am also delighted that you can conscientiously recommend so strongly the fables themselves. They have all come out of my own experience and my own heart, where the best things of all of us come from. My son generally writes the letters; but I told him I would reply to yours received this morning, and we both thought that your handsome notice deserved a gilt-edge copy, which we send by mail, with wishes for a happy Christmas. CHARLES FOSTER.
Philadelphia, Pa., Dec. 21, 1885.

OUR SUPPLIES "JUST SUPERB."

It is with a troubled conscience I inform you at this late date, of the safe arrival of goods ordered Oct. 27. The fact that I have been pretty busy at the office, left me little or no spare time to write; and when I got home in the evening I was so impatient to go to my work-room, and start nailing those nice hives, frames, etc., that I have entirely neglected to let you know how delighted and highly pleased I am with every thing you sent; and although there are ten two-story hives, and all the frames and accessories in the flat, to make them complete, every part fits so nicely, it is a real pleasure to put them together; and, by the way, those iron frames are just the thing for nailing hives; they keep the four sides together splendidly, and each hive must fit the other. I advise every one who has only a few hives to nail to get them; they will pay for themselves, in having a good fit, and saving time.

The sections are very pretty indeed—beautiful, to say the least. They bend up and are driven together so nicely and easily, while the Gray fdn. fastener caps the climax, by fastening the starters in those snow white sections very quickly, and without soiling them in the least, for you hardly need touch them, and that by one simple motion of the foot on the treadle. I was surprised, how you can sell a machine, so perfect in its working, and so neatly and strongly made, for the remarkably small sum of 75 cents.

The extractor is just superb, and I think it can't be beat. The revolving basket is so nicely balanced that, when it is turned, the outside can is not jarred or moved in the least, although not fastened to the floor; and when I put in a couple of combs of honey previously uncapped with the Quinby honey-knife, it threw the honey out so clean that no one would believe they ever contained honey, and not a cell injured. You can imagine how delighted I was, never having seen, much less run, an extractor before, to have succeeded so well for the first time.

And now allow me to beg pardon for being so selfish, as it were, not to share my pleasures, and thank you ere this, for you were really instrumental in bringing them about, by filling my order so satisfactorily and promptly; for to receive my goods, as I did in 12 days from date of order, and 8 days from time of shipment, considering distance, by freight, is quick time, and you deserve the patronage of all who like fair and honest dealing.

CHAS. M. THEBERATH.

Newark, N. J., Dec. 10, 1885.

CONVENTION NOTICES.

The Northern Ohio Bee-Keepers' Association will hold a meeting in the Baptist Hall, in Wellington, Ohio, Friday, January 8, 1886. A special effort will be made to secure a full attendance.

East Townsend, O. H. R. BOARDMAN, Sec.

The North-Eastern Ohio and North-Western Pennsylvania Bee-Keepers' Association will hold its seventh annual convention in Meadville, Pa., Wednesday and Thursday, Jan. 20 and 21, 1886.

New Lyme, O. C. H. COON, Sec.

The next meeting of the Maine Bee-keepers' Association will be held at Skowhegan, Maine, Jan. 19, 20, 21, 1886. WM. HOYT, Sec'y.

Ripley, Me.

The Indiana Bee-Keepers' Association will meet in Indianapolis, Jan. 21, at 1 P. M., in the State Board of Agricultural Rooms, opposite the new Statehouse. We should be pleased to have all meet with us, and hereby send an earnest invitation to come. JONAS SCHOLL, Pres.

Lyons Station, Fayette Co., Ind.

The Sixth Annual Meeting of the Cortland Union Bee-Keepers' Association will be held Jan. 12, 1886, at Cortland, N. Y., in Union Hall, at ten o'clock A. M. It is hoped that all interested in apiculture will make an extra effort to be in attendance at this meeting, also to be present promptly at the time appointed, so that there need be no time lost. Those unable to attend the meeting are requested to send a report of their apiary from May 1, 1885, to Dec. 1, 1885, to the Secretary.

M. H. FARBANKS, Pres.

W. H. BEACH, Sec'y, Cortland, N. Y.

FARM AND APIARY FOR SALE.

160 Acres, 120 in a good state of cultivation, and well fenced; the rest in timber. Good bearing orchard, well watered, and splendid outside range, 4 miles from railroad and County Seat, and a good live town, and plenty of churches, and ¾ mile from school. Will be sold cheap, and on long time. Splendid bee range; lots of basswood and white clover; 24 stands of bees, mostly Italians, in Langstroth hives. For further particulars, address old JAMES HUMPHRYS, BOX 200, MT. AYR, RINGGOLD CO., IOWA.

HAVING MOVED TO NEWARK, N. J.,

My friends will please take notice, while reading my advertisement, of the change of address.

F. Holtke, 89 Waverly Place, Newark, N. J.
In care of Mrs. Kitterer.

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was $40.00, but we will now sell it at half price, or $20.00.

A. I. ROOT, Medina, O.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this deparment, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not. **CLEMONS, CLOON & CO.,**
15-2db **Kansas City, Mo.**

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.
10	3	3 rolls of 75, 72 s. f.
12	2	2 rolls, 100 s. f. each.
20	3	3 rolls of 166 s. f. each
22	4	2 rolls of 181, 1 of 169 s. f.
24	6	4 rolls of 200, and 1 of 180 s. f.
26	71	22 rolls of 217, 38 of 216, 2 of 195, 1 of 156, 2 of 215, 1 of 210 s. f.
28	16	13 rolls of 233, and 2 of 234, s. f.
34	7	5 rolls of 281 s. f.
36		
38	37	28 rolls of 316, 3 of 285, 2 of 317, 1 each of 190, 632, 126, and 215 s. f.
42	1	1 roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
46	1	1 roll of 152 s. f.
48	12	9 rolls of 400, 1 of 100 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
20	1 roll of 155 s. f.
22	1 roll each of 88, 143, 92 s. f.
24	43 rolls of 200 sq. ft. each; 1 each of 80, 96, 120, 168, 190, 100 150 140 sq. ft.
26	58 rolls of 216 sq. ft. each; 1 each of 195, 195, 201, 200, 201, 227, 204 sq. ft.
28	76 rolls of 233, 6 of 224. 3 of 219, 8 of 222, 7 of 224, 2 of 219, 1 of 117 sq. ft.; 1 each of 70, 210, 245, 257, 240, 215, 110 93, 82 sq. ft.
30	36 rolls of 250 sq. ft.; 1 each of 82, 137, 225, 117, 125, 125, 220, 227, 237, 235, 275, 240, 157 sq. ft.

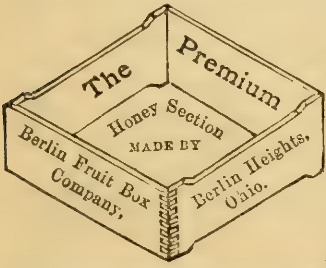
MINUTES OF THE DETROIT CONVENTION.

The proceedings of the N. A. B. C. at Detroit is being published in pamphlet form, and a copy will be sent to each member of the society who was in attendance. All others who so desire will receive a copy on payment of 25 cts. to the society.

FRANK L. DOUGHERTY, Sec.
Indianapolis, Ind.



Awarded

First Premium twice, and the only instances they ever competed, in 1884 at Michigan State Fair, and in 1885 at the Inter-State Fair, held at St. Joseph, Mo. The excellence of these sections is acknowledged by many leading bee-keepers amongst whom are the following, who handle and use them:

Chas. Dadant & Son, Hamilton, Ill.; F. L. Dougherty, Indianapolis, Ind.; M. H. Hunt, Bell Branch, Mich.; Hemphill & Goodman, Elsberry, Mo.; G. W. Demaree, Christiansburg, Ky.; Theo. Thomas, Pleasant Valley, N. Y.; H. R. Boardman, East Townsend, Ohio.

The last-named gentleman writes us, "The lot of sections I got of you (10,000) were very nice and perfect. I am not satisfied in saying I was pleased with them—I was delighted. They were bright and perfect as new-made coin. I have no hesitancy in saying that your make of sections is superior to any I ever saw. There is practically no breakage in folding. In trying them I folded 1000 without breaking a piece."

Our improved facilities for manufacturing these sections enable us to offer them at greatly reduced rates. Send for price list. Address as above. We also make the best berry-baskets in the market.
2-3-4d

WANTED.—To exchange strawberry and raspberry plants for $1.00 or tested queens, or pounds of bees (in spring). Address 2tfdb

Jan. 11, 1886. 57 Chatham St., Boston, Mass.

KANSAS CITY. — *Honey.* — Sales extremely light, and prices very low. Choice comb, 1-lb. sections, 14@15c; 2-lb., 12@13c. Dark fall honey, 1@2c. less. Extracted, very dull, and slow sale. We had to unload some first-class extracted honey this week at 5c, and stocks continue to accumulate.
Beeswax, scarcer and higher, 22@25c.
Jan. 7, 1886. CLEMONS, CLOON & CO.,
Cor. Fourth & Walnut St's, Kansas City, Mo.

CHICAGO.—*Honey.*—The market has changed but little since last quotation, there being a moderate demand for all grades and styles. Perhaps extracted is in better demand than comb, but both are needed here, as the supply is light. There has always been a good demand for honey about the beginning of February, and the stock should be here to meet it. R. A. BURNETT,
Jan. 11, 1886. 161 S. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—Since the holidays, the demand for honey has been very limited in all lines; values remain unchanged. Choice white 1-lb. sections, 14@15; 2-lb., 12@13. Second grade very hard to sell at 10@12. Old honey, 10@11. Extracted, 7@8. *Beeswax*, very scarce at 25. A. C. KENDEL.
Jan. 9, 1886. 115 Ontario St., Cleveland, Ohio.

MILWAUKEE. — *Honey.* — The demand for choice white-clover honey is very fair, and supply not large. I can encourage shipments. Extracted in very good demand. I will quote, 1-lb. sections, white, 15@16; 1½ and 2-lb. sections, white, 15; dark honey, 12½@14. Extracted in kegs and bbls., white, 7½@8; extracted, in kegs and bbls., colored, 6@6½.
Jan. 5, 1886. A. V. BISHOP,
142 W. Water St., Milwaukee, Wis.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this deparment, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not. **CLEMONS, CLOON & CO.,**
15-2db **Kansas City, Mo.**

LOOK HERE!

To introduce my strain of pure bright Italians, equal to any in the United States, I will offer tested queens, $1.00 each; extra fine, selected, $1.50 each; one-frame nucleus, consisting of one extra select queen, one frame of brood, ½ lb. bees, for $2.00. If you want any bees, send me your address on postal and I will send you sample by return mail. Beeswax or honey taken in exchange.
22tfdb **THOMAS HORN,**
Box 691, Sherburne, Chen. Co., N. Y.

Bee-Hives, Honey-Boxes, Sections.

LARGEST BEE-HIVE FACTORY IN THE WORLD.

CAPACITY, 1 CARLOAD OF GOODS PER DAY.

Best of goods at lowest prices. Write for Price List. 1tfdb. G. B. LEWIS & CO.,

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error.

WANTED.—To exchange one-half bushel of extra fine white-clover seed for alsike-clover seed. 19tfdb M. A. GILL, Viola, Richl'd Co., Wis.

WANTED.—To exchange or sell. Friends, I have 15 pairs of the celebrated Bonney's stock of Brown Leghorns that I will sell at $3.00 per pair, or will exchange for good beeswax at 25 cts. per pound. Circulars free. Ref., A. I. Root.
24tfdb A. H. DUFF, Creighton, Guern. Co., O.

WANTED.—To exchange, Scott's Commentary on the Holy Bible, 6 vols., quarto, bound in sheep, in good order, weight 19 pounds. As I have other commentaries, I will exchange this for something else useful. Address A. H. VAN DOREN,
24tfdb Liberty, Bedford Co., Virginia.

WANTED.—To exchange golden-willow cuttings for Italian queens. I will book orders now, and send the willows as early as will do next spring; queens wanted in May and June, 1886. 2 dozen cuttings for a warranted, and 4 dozen for a tested; also one weeping-willow cut with each dozen. Will send by mail. S. C. FREDERICK,
24, 5db Coal Vale, Craw. Co., Kan.

WANTED.—To exchange pure-bred German Canary birds; also Brown and White Leghorn eggs in season, for beeswax, sections, or Italian bees. F. H. CHAPIN, Hinsdale, Catt. Co., N. Y.
1-2d *Dealer in all kinds of country produce.*

IF you wish to exchange strawberry, blackberry, or raspberry plants for Italian bees, send list of varieties and prices to E. A. GASTMAN,
1tfdb Decatur, Macon Co., Ill.

WANTED.—To exchange, a Barnes foot-power circular saw, with three saws and two mandrels; also one circular-saw mandrel, for either honey or poultry. Make offers.
1dtfb OTTO LESTINA, Derby, New Haven Co., Ct.

WANTED. — To exchange Italian bees and queens for a second-hand engine, Shipman or Payne & Sons. L. HEINE,
2d Bellmore, Queens Co., N. Y.

WANTED.—To exchange a buzz and scroll saw combined, one polyoptican, new, one Smith American cabinet organ (catalogue price $210.00), all in perfect condition, for Plymouth Rocks, Chester or Poland pigs, Holstein or Jersey calves, or young cattle. L. W. LIGHTY,
2tfdb Mulberry, York Co., Pa.

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY & HOME INTERESTS.

Vol. XIV. **JAN. 15, 1886.** **No. 2.**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00, 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

MORE ABOUT THE BEE'S EYES.

A TALK TO THE JUVENILES ON HOW TO COMPREHEND MERE NUMBERS.

As Prof. Cook has opened the way, I now venture forth with a few more notes upon the bee's eye—such facts as I have been enabled to glean from the field of the microscope. This is not intended to supplement Prof. Cook's able article on the above subject, but is simply the result of independent research. I therefore will take up the eye of a bee, presenting it in a slightly different phase.

Let me see—I was going to write to the little folks, so I am. First, I desire you to read Prof. Cook's article over carefully, for you surely will find it interesting; then if you choose you can see what I have to say.

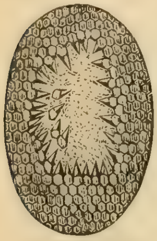
The compound eyes that Prof. Cook told you about are called "compound" because there are a great number of eyes in one. If I should tell you that in one of these compound eyes there are over 3000 little eyes you would hardly know how many this meant. When I tell you that the sun is over ninety millions of miles away, you could then form but a small idea of its immense distance. Figures have but little meaning to us, unless we can have something for comparison. Astronomers — men who study the stars—have a way of comprehending distances, and I will try to explain it so you can understand it.

You are accustomed to regard this earth as very large. You can travel a whole week over its surface, and then you will have gone over but a small portion of its circumference. Now, did you ever think that light travels? If you are old enough, and have been at school long enough, you will find that it travels exceedingly fast. Why! it can go around this great earth more than seven times a second; and yet, with this enormous speed, wise men tell us that it takes eight full minutes for the light to travel from the sun to our earth. In other words, it takes eight minutes for the light to travel 90,000,000 of miles—the distance from the sun to us. Now, can you understand what a lot of ciphers mean? If you do not, get your mother to help you. A moment ago I told you that a bee had, in one of his compound eyes, over 3000 simple eyes, or 6000 in both his large eyes. These figures I obtained with the aid of my microscope by counting a certain number, then estimating. By referring to Carpenter—an authority on the microscope—I find that a fly has in two of his compound eyes 4000 simple eyes; the cabbage-butterfly, 17,000; dragon-fly, 24,000.

These numbers are by no means as large as those standing for the distance to the sun; yet three or four thousand, I fancy, will have little meaning to our little folks. Let me see—a *very* large hall or church will hold perhaps three thousand people. Now, suppose you crowd every one of these people into an area of little over an eighth of an inch square, how small do you suppose each person would become? He would be about the size of one of these simple eyes in the compound eye of a bee.

Little friends, I have given you these comparison in order that you may better understand what mere numbers signify, and also that you may better comprehend how very small are the simple eyes of the bee.

Let us next glance for a moment at the general appearance of the bee's eye, a cut of which appears below, showing the form of each simple eye, or "ocellus;" their combined surface resembles, somewhat, sealed comb honey (or brood). In the drawing, the simple eyes are exaggerated; for if given in their exact proportion they would be hardly visible. Through the microscope, however, these simple eyes appear like a lot of little beads nicely imbedded over the surface of the large eye, and I do not know of any part of the bee that is more beautiful under the microscope than this.



EYE OF A BEE.

You notice in the engraving, that part of the eye looks as if the central portion had been torn out. This is to show the shape of each little eye when dissected. You observe that the outer surface of each is hexagonal (having six sides like honey-cells), and tapers down to a point. To this is attached the optic nerve, communicating with the brain. Perhaps you would liken the whole to a sunflower head filled with ripened seed, the whole head answering for the compound eye, and the separate seeds the simple eye.

When we reflect that each one of the simple eyes is so small and yet so perfect, having nearly all the parts belonging to our eyes, are we not again led to say, "How wonderful are thy works, O Lord!"? Yes, he has made great worlds, millions of miles away, and yet even the little insects have not been neglected, so perfect are they. ERNEST R. ROOT.

UPPER ABSORBENTS.

CAN BEES WINTER IN OPEN-MOUTHED BOTTLES?

THERE is no business or occupation in existence, that I am aware of, in which there are so many prominent, vital questions unsettled, as in bee-keeping. There are numerous points, important to all and doubly so to the beginner, on which we will find leading and successful apiarists holding diametrically opposite views. We see this at every bee-keepers' convention and in nearly every bee-journal we read.

To the experienced bee-keeper this want of unity in thought with the argument which it brings, is not only of no injury, but often of decided benefit, by leading him to question more closely his reasons for his own line of action, and thereby detect any possible flaws therein. To beginners, though, whose ideas are not yet matured by experience, this variety of opinion is, to say the least, somewhat bewildering. Still there is no help for it. By discussion we shall the sooner arrive at truth; and it is but justice to the beginner to present both sides of the question, in order that he may decide for himself on those points where "doctors disagree." Very often what is right for one locality or system of management is all wrong for another, and so both sides may be right, and no doubt frequently are. We are apt to get so deep into our own groove that we do not see our neighbor in *his* groove, although it may run almost alongside of our own, and coming out at just the same place.

I am led to write this by the article which appeared on page 824 of Dec. GLEANINGS. The writer takes alarm at the statement by Mr. Heddon, that he is "becoming of the opinion that our upper absorbents are usually useless and ofttimes worse," and expects the editor, as a matter of course, to join him in attacking the heresy. I have read Mr. Heddon's reply with interest; but as he is probably busy with his new book and reversible hive, he does not go into the subject with his usual thoroughness.

Several years ago, in giving in GLEANINGS the results of some extensive wintering experiments, I said that, while it seemed to make little difference during the winter whether an enameled cloth or a porous covering were used over the bees, a porous covering was a decided detriment during the spring months. Further experiments since then have convinced me that, if other conditions are observed, there is never any real advantage to be derived from upper absorbents, while with a small swarm or a large hive, or at any time when brood is being raised before warm weather comes, there is a great disadvantage from their use. I find, too, that many of those most successful in wintering have come to the same conclusion. Moreover, I have no doubt that the reason why bees in box hives, without care, often winter better than those that have the advantage of all the modern improvements is that the latter are frequently ventilated to death, while the former are more often allowed to hermetically seal the top of the hive, and absorbents are never thought of.

I consider that the essential points in outdoor wintering are, 1. Plenty of good honey, or its equivalent, with but little pollen; 2. Strong colonies; 3. A contracted hive, a covering impervious to moisture, and a large entrance; 4. A protection from the cold (on top, and, if possible, on all sides) of chaff or other non-conducting material, the thicker the better.

To carry out this system, as soon as spring comes the bees should be crowded on still fewer combs, and the entrance made quite small, until the size of the colony and the heat of the season make enlargement necessary.

WHY ABSORBENTS ARE INJURIOUS.

Bees at all times exhale a certain amount of watery vapor. In cold weather this must pass out of the hive, or be condensed on its combs or walls as water or frost. To prevent this condensation many place porous materials inside the hive, which are supposed to keep the hive dry by absorbing the moisture. Very often they do this very well for a time; but if no provision is made for drying them they become damper and damper as the winter continues, until finally they can hold no more moisture. Any thing wet is, under such circumstances, necessarily cold, and this damp cushion often proves a veritable "wet blanket" on the prosperity of the unfortunate colony, extending its malign influence long after cold weather is past, compelling the bees to dry this soaked and often frozen cushion by the heat of their bodies before they can be comfortable.

Instead of absorbents some employ upper ventilation, carrying the moisture out of the hive along with an upward current of air through the top. There are but few who advocate that this current should be unrestrained, as when an opening in the top of the hive communicates directly with the outer air, because the folly of this course is usually easily seen after a hard winter or with weak colonies. The heat of the colony is carried off so rapidly that either all die during some cold snap, or they dwindle away by degrees and die in the spring, or come through with but a fraction of a working force.

Others prefer a medium course; viz., upward ventilation through a thick layer of chaff or other porous material. Here the chaff is not really an absorbent, but only serves to restrain the upward current of air. If any moisture is absorbed it is soon dried out by the rising air. This is much better than unrestrained upward ventilation, or absorbents without upward ventilation, but it is also very wasteful of the heat of the colony. Any thing like an upward current is injurious, causing the bees to become uneasy, and consume a greater quantity of food, rendering them more liable to starvation and diarrhœa.

It is scarcely necessary to remind any of the readers of GLEANINGS that warm air is lighter than cold, and therefore has a tendency to rise; that the top of an apartment containing any source of heat is warmer than the bottom, or that, if a hole be made in top of such an apartment, a draft will be created which will lower the temperature of the room by removing the warm air; neither is it necessary to remind you that moist air is heavier than dry air, especially when cool.

In the face of these facts I can hardly see why bee-keepers follow the unscientific and unnatural plan of using absorbents or upward ventilation to remove the moist air which would run out of the hive itself if permitted, carrying very little heat with it. "All-out-of-doors" is the best, cheapest, and most extensive absorbent of moisture we can find. To gain this end, the entrance should be large—I would have it not less than 12×⅜, the wintering apartment small, so that the bees can warm all parts of it, and its walls protected by some non-conducting material, the thicker the better, in order that they may be kept warm so that moisture will not condense on them. These walls, sides, and top, should be of some material impervious to air or moisture; then the watery vapor generated by the bees, being heavier than the air, will sink to the bottom and flow out at the entrance, while the warm air will remain confined at the top of the hive.

The prime cause of our wintering troubles is cold. Retention of moisture in the hive, or ventilating it out at the top, must lower the average temperature, which is something we should carefully guard against. 8—J. A. GREEN, 85—100.

Dayton, Ill., Jan. 6, 1886.

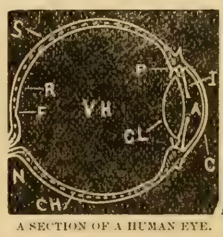
Friend Green, your reasoning is good, and the most of it I am prepared to follow. But it seems to me you are going a little to the extreme when you recommend a small wintering apartment, impervious to air or moisture. Of course, you recommend that this small apartment should be well protected by some non-conducting material, and that the entrance be large. I agree with the latter, and may be with the whole of it; but to be sure we understand you exactly, suppose you put your bees into a bottle having a large mouth, the bottle to be just the size to contain the colony, and to be protected abundantly by warm packing over all the bottle except the mouth. Would this be just the thing? I am rather inclined to think it would, if the mouth of the bottle were of just the right size; and 12 inches by ⅜, or an equivalent, would probably be about right for an average colony. You will see, by looking at the A B C book, that I come pretty near on to your ground, though I confess I should have feared to recomend a glass bottle. I say *glass*, because glass is a better non-conductor of heat than metals, or, I might have said, a water-tight tin box. Now, if your position is the right one (that we can confine every bit of the animal heat, provided we keep the frost entirely away from the impervious covering), I do not know but we are going to make a big step in this matter of wintering. I notice the poultry journals are recommending just this thing exactly. Let the fowls roost in an air-tight apartment, except an opening below, where they hop up on to their roosts. This, of course, is for zero weather.

VISION IN INSECTS.

AN INTERESTING TALK ON EYES IN GENERAL.

I SUPPOSE many of the readers of GLEANINGS know that the eye is a very complex organ. The window of the eye—the cornea, marked C in the drawing—is transparent as clearest glass. This bends the rays of light that pass it, as does water. We all know that this is why the stick in a glass of water appears to bend. The rays of light do bend, and so the stick appears to bend. The aqueous, or watery humor, A, back of the cornea, is simply a filling; it varies the ray of light leaving the cornea, almost none at all. The iris, I, is what gives color to the eye. It is the window-curtain, which the eye dexterously raises or lowers as it wishes more or less light. This is to the eye what the diaphragm is to Ernest's microscope. The reason that the iris is colored is from its containing a coloring material called pigment. The same material in the hair or skin gives color to those parts.

The albino has none of this pigment, so his hair is white, his skin pink as a baby's — the blood-vessels show through—and his eyes are pink for the same reason. The albino can not close the shutters, as his iris is transparent, and so in daylight his vision is dazzled, and, like an owl, he can see better by night than by day.



A SECTION OF A HUMAN EYE.

The pupil is the little black hole in the center of the iris, where all rays of light must enter every eye —except those of the albino. This little port-hole is black, only because it opens into a black chamber. Just back of the pupil and iris is the beautiful crystalline lens, C L. This is a double-convex lens in form, and no crystal is clearer. My students, in their dissections and study of the eye, always exclaim at the marvelous beauty of this crystalline lens. This crystalline lens, like the cornea, bends the rays of light still more, so that all from any point of an object wherever they may enter the eye come to a focus on the retina, R, the part of the eye that is able to perceive or take note of light and color. This focusing is absolutely necessary to perfect vision. In near-sighted people the rays are bent too much; in old people too little. The crystalline lens bulges more as we look at very near objects, and less as we gaze at things distant, and so we are able to see distinctly in every case. In "cataract" this crystalline lens becomes opaque, and the person, of course, is blind in that eye. The operation for cataract consists in the removal of the crystalline lens, which is often done in case of cataract in both eyes. Isn't it marvelous that a surgeon can cut right into the eyes, take out a part, and thus restore vision?

Back of the crystalline lens is the jelly-like, perfectly transparent vitreous humor, V H. This seems to be a sort of packing to fill up the space between the crystalline lens and retina. Of course, it must be transparent, else how could the light pass to the retina? The retina, R, is the expansion, away back in the eye, of the optic nerve. This retina is the tell-tale. It reports to the brain all the beauty of form and coloration in the outside world. What a terrible blank in the life, when no such reports are made! The retina is very complex, and I will not describe it.

Just outside, or back of the retina, is the black choroid coat, the dotted line marked C H. This is black because of pigment, and it also contains the blood-vessels that nourish the eye. To see well, the eye must be a black chamber, and so this choroid coat is black; the same is true of the microscope and the photographer's camera. Indeed, every perfect optical instrument has a black lining.

Now, all insects—and so our bees—have eyes of similar structure to our own. The bees have two large compound eyes—one on each side of the head, and three simple eyes. The compound eyes consist of many simple eyes close together. Sometimes each compound eye is made up of thousands of simple eyes. Each one of these simple eyes has a cornea, humors, crystalline lens, and retina, from which a nerve runs to the brain.

We detect form in objects, it is supposed, because we have two eyes, and see a little more to one side of an object with one eye, and to the other side with the other eye. Müller held that bees and all insects could, in the same way, detect form as well as motion and color. His was termed the mosaic theory of vision. Exner opposed this view, and held that insects could not perceive form. Plateau, of Belgium, has just reported to the Belgium Academy many experiments, and concludes with Exner that bees can not detect form. He also says that the simple eyes are imperfect, or rudimentary eyes. That, as he says, bees have no better eyes than flies, is certainly a reasonable conclusion.

Now, what do our bee-keepers say to this theory, that bees can not detect form? Are we not certain that a slanting board, or a slight change in position of the hive, is at once detected? I believe facts, as gained in that large laboratory, the apiary, are often stronger than facts gleaned in a much smaller way by the scientist in his laboratory.

Again, theory would assert quite as readily that the compound eyes could, from their peculiar structure, detect form as quickly as motion. True, motion is ever throwing the image in different simple eyes; but varying form would also affect different simple eyes, and why might not different eyes, as well as a varying position in two eyes, detect form? That the single simple eyes are imperfect, is, I think, true. Often they are so covered with hairs as to make them useless; and the very fact that in many insects they have been snatched away entirely, suggests that they are useless in all. If any reader wishes to study an eye, let him procure a head at a slaughter-house, freeze the eye after it is carefully cut out, then it can be dissected and examined in all its parts. A. J. Cook.

Agricultural College, Mich.

Thanks for the very able manner in which you have treated this subject. I am sure our little friends will find great pleasure in reading from your pen. It was my intention to give the children a little talk on the eye, but I felt myself not "big enough" for the task. I had thought of writing you for what information I lacked, but I see, by a kind of special providence you have anticipated my questions. In another column, since you have opened the way, will be found a few more notes on this subject.

How I should enjoy being one of your students in this special kind of work! It was my hope, after finishing my classical education, to take a special course under you; but fate, if that be the term, has denied me that privilege. Ernest.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

We respectfully solicit the aid of our friends in conducting this department, and would consider it a favor to have them send us all circulars that have a deceptive appearance. The greatest care will be at all times maintained to prevent injustice being done any one.

MONEY FOR THE POOR MAN; THE GREAT ACME PENETRATIVE.

UNDER the above title, or something like it, you will notice, in many of the papers, a picture of a stump on fire, with an advertisement of a chemical that will be sent for a dollar, sufficient to burn any stump, green or dry, and the dollar's worth will burn up, root and branch, 12 large stumps or 18 medium-sized ones. The advertisement says the compound contains no saltpeter. We sent our dollar and obtained a pinkish-colored compound that *does* contain saltpeter. A circular came along with it, headed, "Money for the Poor Man." On the last page of said circular are quite a number of testimonials from farmers, relative to the wonderful results obtained by the use of this Acme penetrative. Every one of these testimonials, however, is destitute of address and date. The advertisement comes from F. E. Fross & Co., New Carlisle, Ohio. In writing to the above firm in reference to sending out such testimonials they make no reply. The paper wrapped around the Acme penetrative was part of an advertising circular of a firm in New Carlisle who formerly dealt in bee-supplies. The *Ohio Farmer* contains a caution to farmers about a new kind of seed wheat, also coming from this Fross & Co., with the name spelled a little differently. The *Rural New-Yorker* also has a caution in regard to swindles about a chemical for burning out stumps. The whole matter seems to be in some way mixed up with the names of those who formerly advertised bee-supplies from New Carlisle, therefore our bee-friends will probably get an abundance of circulars from this place. If there are some honest men doing business in seed wheat or bee-supplies at New Carlisle, we would caution them about letting their name be mixed up. or their circulars, with F. E. Fross & Co. If they want a hearing, we shall be glad to give it.

I should have said in the outset, that the directions for using this Acme penetrative tell us we must wait two months and a half after putting it in the stump, before the stump is ready to burn; so you see they have two months and a half to run their advertisement before any one can gainsay their claims.

HEDDON'S NEW BOOK, "SUCCESS IN BEE CULTURE."

ALSO SOMETHING ABOUT HEDDON'S NEW HIVE.

THE book in question is paper bound, 128 pages. It is profusely illustrated, but we are sorry to note that a good many of the new illustrations are not engraved as they should be; in fact, the book explains that the engraver did not do his duty. Friend Heddon has evidently had experience in trying to make engravers picture things as they are, instead of some heedless plan of their own. It is an excellent plan to have the engraver make a drawing first on the block, and don't let him engrave it until the drawing is as you want it. The book contains many terse and valuable thoughts, characteristic of friend Heddon's vigorous brain. And now, however much we may find in the book to criticise, it is well worth half a dollar. The food for thought that it gives to every bee-keeper, young and old, it seems to me, is well worth the cost of the book. I think, however, it should be read in connection with other works on bee culture, as so many things are passed over in a brief way, from necessity, on account of the size of the volume. The principal feature of the book is, to me, Heddon's new hive. The hive we talked so much about a year ago is described in the book; but the new one is to throw the old plan entirely aside. The principal feature of the new hive is in making the brood-apartment in two stories. Each story contains frames only 5⅜ inches in depth. These frames are closed-end frames. On account of their shallowness this will probably be no great obstacle in the way of manipulation, and friend Heddon claims that almost all necessary operations can be performed without removing these shallow frames at all. To facilitate this, the top and bottom bars are made only 13-16 inch wide—a little narrower than ⅞, you will notice. Years ago I thought of making a hive without frames, somewhat on this principle, having the combs shallow, and pretty widely spaced with narrow top and bottom bars. My plan then was that we could reach down between these narrow top and bottom bars, widely spaced, so as to cut out queen-cells, or see brood, even to a depth of two or three inches; turn the hive over, and a depth of two or three inches on the other side would put all the combs under our control or under our eye—at least without taking the combs out. Two of these shallow brood-nests give a capacity of an ordinary lower story. The sections are put in shallow wide frames. It is a little amusing to see friend Heddon go back and declare in favor of wide frames, and *separators* also, after the way he has denounced both for a year or two back. If I were he, I would be a little mild in denouncing any thing, especially if I expected to change my plans within a year or less. It is true, however, that a very progressive mind must change in opinion as it explores new and different fields. The wide frames, with separators to hold the sections, are exactly the same as the case for three section boxes, which has been for so many years illustrated in our price list, only it is made to hold four sections instead of three. Both the brood-frames and wide frames are closed-end, and rest on a strip of tin at the bottom of the hive or case. Like Quinby's closed-end frames they have no projecting arms, but are alike either side up. This makes the frames reversible, and the hive is also reversible. Of course, you can not get the frames out of any hive or section unless it is a certain side up. The ends of these closed-end frames come close against the ends of the hive, for the frames themselves, outside dimensions, are only 1-16 inch less than the inside of the hive.

A good many things may be accomplished by dividing a hive horizontally into two sets of shallow frames. It occurred to me at once that this shallow hive would be a splendid thing for shipping bees, especially so since friend H. makes the whole thing solid, and fixed by a wooden thumbscrew to put through the hive at the proper place to screw up the frames tight, the screw striking the middle of the end-bars of the frames. In this shape it is reversible at pleasure. The bottom-board is cleated around its outside edge so as to give the necessary bee-space when the first story is placed on the bottom-board. Friend Heddon enumerates a great many advantages to be secured by this shallow frame. I believe he has not mentioned, however, what seems to me to be a great and serious disadvantage. It is this: He is dividing the brood in every comb right through the center, or heart of it, and interposing two sticks and the ⅜-inch air-space. It is true, the queen may be made to do very fair work in a comb only five inches deep; but from the way in which queens seem to prefer to lay their eggs in a circle, say from six to eight inches in diameter, I can not think you can get this circle down to less than five inches without loss. It is true, she may make the circle embrace the combs in the upper story as well as the combs in the lower story; but then we have this division above spoken of in the heart of the brood-nest.

Friend H. has a patent on the hive. Of course, he has a perfect right to have a patent on it if he thinks it is the better way; but in view of the fact that so many of the features of his new hive have been in common use, if I were in his place I think I would not have had a patent on it. I hope he will excuse me for venturing to give my advice when it has not been asked. We have discussed patents so much already, I do not believe it will be worth while to go all over it again; but that these shallow frames will answer tolerably well, has been proven repeatedly. T. F. Bingham has used for years a hive with frames only six inches in depth, and Heddon's are only a little shallower, as you will see. R. Wilkin, when he used to live in Ohio, also used a shallow-depth frame; but after a great many years of experiment with them he abandoned them. The closed-end feature is not new; the idea of putting screws through the side of the hive to tighten up the frames together is not a patentable idea. The whole arrangement, however, is sufficiently different from any thing heretofore in use, and friend H. is, without question, entitled to a valid patent, if he thinks it best to have one.

We should like to know how many seasons he has tested this, if more than one. I should like to give illustrations of the whole hive; but I confess I should want some better engravings than are found in the book. If friend H. will send me a hive just right I will have some good engravings of it made, at my own expense. We can mail the book on receipt of price, 50 cents.

DISASTROUS WINTERING.

HOW THE BROKEN RANKS WERE RECRUITED.

IN 1884, white clover yielded bountifully in this vicinity. I began the season with 74 colonies, which I increased by natural swarming to 102, besides receiving a nice harvest of light honey. There was no fall honey. In the fall I removed sixteen miles to a new home. I found it quite a task to remove my bees. I took charge of their removal myself, and did it as carefully as I could; still, I lost one colony by the combs melting down.

At my new home I arranged my hives south of the house. They were arranged in six rows, facing south. The hives were painted, and looked nicely, standing on the green grass beneath the trees. I remember looking at them from the window, and thinking of them as an army placed there to defend my home from want.

As the fall flowers yielded no honey my hives grew light in stores, and less populous. I fed, doubled up, and cared for them until they were reduced to 93, and at that time I was compelled to leave home for a time. When winter set in my wife hired two men who carried the bees into the cellar. On March 26 I carried them out and placed them on their stands. I found many dead, and none seemed more than half alive. That evening I looked out again at my army, but its ranks were fearfully broken. The spring in this region was cold and backward; and although I fed, nursed, and tended, they dwindled, were robbed, and swarmed out, until my army was reduced to 17 colonies. Of these, 5 might be termed fair; the other 12 were little more than nuclei. When I looked out at those 17 colonies, all that remained of my army, I exclaimed, "How are the mighty fallen!"

To relate this tale of disaster would do no good unless the supposed causes were pointed out. I believe that, on account of the scarcity of fall honey, there was but little brood raised in the fall, and therefore winter found my colonies weak in bees, and those few mostly old bees, destined by the law of their nature to die before spring.

Last winter is destined to be remembered on account of its intense and long-continued cold. As I was in a new home the cellar deceived me, not being so frost-proof as it appeared. As my hives were not populous, it was impossible for the small cluster to keep up the heat necessary to a healthy condition in that cold cellar. Then to crown the disaster, after they were placed upon their summer stands I think the weather was unfavorable for them as it could well be, and the result was spring dwindling.

From the reasons I have mentioned, the spring of 1885 yielded me a bountiful harvest of empty hives and combs. After duly considering the condition of affairs, I went out among the farmers to buy bees, and succeeded in picking up 38 colonies in box hives, at an average cost of $3.87 per colony, and therefore began the season with 55 colonies. By what is termed the Heddon method I transferred those I purchased to my own combs and hives. The past summer was not counted a honey year in this vicinity, yet I increased to 75 good colonies, and received enough honey to pay for the colonies purchased. Fearing a repetition of the experience of last spring I prepared my cellar with care, banking up the house, and closing up every crevice with lime mortar. I also placed a stove in it, so that, if the thermometer should fall too low, a fire could be started. Up to the present time my bees seem to be wintering nicely. W. D. RALSTON.

Hopkinton, Iowa, Dec. 31, 1885.

REPORTS ENCOURAGING.

158 LBS. PER COLONY SECURED BY THE DIRECTIONS GIVEN IN A B C.

I HAVE no bees now, but shall open up an apiary in the spring, for it is the best paying business that I ever worked at. I am told that bees did not do well here this season. I did some transferring for two parties, and they seemed to have done well enough. The great trouble is, the bees don't get the attention they should. The first four years after I read your A B C I made 158⅓ lbs. of salable honey per colony, per annum; the highest yield, 300 lbs. per colony, two years ago.

East Newbern, Ill., Nov. 8, 1885. R. S. GIBERSON.

But, friend G., you don't tell how many colonies you had. If only three or four, the report would not be nearly as large as if you made forty or fifty give that amount.

$72.00 RECEIVED, AND NO OUTLAY.

I must send in our report, even if it *is* poorer than ever. We started last spring with 26 poor weak colonies (as we lost more than half of our bees last winter and spring), and increased to 55; went into winter quarters with 54 nice rich colonies. We did not get much honey this year, as the bees did not make any honey from the first of July to September. Then there was a couple of weeks that there was quite a flow of honey, and they filled up their hives, and made a very little surplus. We sold about 470 lbs. of honey; came to $72.00. Not a very big paying summer's work; but one thing is in our favor, we were at no expense.

LOUISA C. KENNEDY.

Farmingdale, Ill., Dec. 29, 1885.

PROF. COOK ON THE PRESENT ASPECT OF TEMPERANCE.

ALSO SOME VERY KIND WORDS IN REGARD TO GLEANINGS.

DEAR FRIEND ROOT:—You already know that I have always approved your course in making GLEANINGS the medium of other thought and suggestion than that which belonged solely to the bee-keeping industry. I think you have done no little good, perhaps as much in helping people to happier and better lives, as in advancing bee-keeping. The firm hold and warm place which GLEANINGS has in the hearts of its patrons is proof enough that I am right. The people recognize the great truth, that we do not live by bread alone. In your calling the attention of so many to the words, life, and teachings of Him in whom was no guile, and who "spake as never man spake;" who gave to the world such inspiring words as, "Let him that is without sin cast the first stone," and, "Father, forgive them, they know not what they do," you have builded, though perhaps not better than you knew, but so well that the structure reaches to hearts all over the land, and bears hope, cheer, and encouragement. Then, again, your good wholesome words on the tobacco habit! Who can tell how many men are cleaner for your timely exhortations? I have sometimes wondered, if Shakespeare had lived in our day, when tobacco drags its horrid presence into so many homes, if he would have said: "What a piece of work is man! so noble in reason, ... *in action so like an angel!* the *beauty* of the world!" for when we think of it, what more irrational than that men should form and continue a habit that renders them filthy and disagreeable to associates; robs — yes, worse than robs the pockets, often injures, and even destroys health, and, worst of all, blunts those finer feelings of courtesy and good taste which it behooves us all so studiously to cultivate? I am glad, dear brother, that you have fired such telling shot into the ranks of the army of tobacco-slaves. It must have pleased you to see how very few at Detroit used tobacco; and those who did, so far as I saw, were those whose locks tell that they are beyond the years when advice finds ear, or good counsel takes root.

But there is another habit whose wrongs, whose evil tendencies, whose blasting work of sin and ruination, so pales the tobacco habit that you and I, and every patriot, not to say Christian, feels that to stay its ghastly tread would be the glory of the age. Slavery blasted the hopes and lives of only a portion of one race: intemperance reaches its horrid, blasting hand into the homes of all races, and is cursing homes in every land. So great an evil can not long go unchecked. If, as I believe, the John the Baptist in this glorious liberation is to be education, then GLEANINGS, and every voice and press in the country should make bold strokes toward this desired enlightenment.

Prohibition has always had my sympathy, and I would gladly give it my heartiest support; but it seems not to touch the key to the problem, and is more helpful as an index to improved sentiment, I fear, than as an active means in destroying the evil, which all good men would see banished from the world. It seems to me that at present, prohibition is not practicable. So many of our best temperance workers have no confidence in it, and so give it no aid, that our ranks in that line are fatally weakened. Again, prohibition does not prohibit where prohibition is most desired. True, if it work only a partial stay of the curse, it is good; but if it holds back some stronger force that would wield a far mightier power, then surely its presence as a law or a scheme to be urged, is unwise and impolitic.

We all know that prohibition, in places where there is not a moral force to sustain it, is inoperative; and the fact that it fails where most needed is made a strong argument against it. Again, while many of us shrink from licensing any evil, least of all so terrible an evil, yet if a license will stop in any degree the sale and use of this demon alcohol in places where prohibition is impotent to do good, then surely on that axiomatic authority, of two evils choose the least, we should favor license under a heavy fee. Now, why would not a law like that already adopted in some of the States suit all, do most good, and get the support of all temperance people? That is a license with a heavy fee, in conjunction with local option in every town and village or city where it can be carried? That gives us prohibition where it can do any good, and does not remove license where only license can be effective. It seems to me this is where we can all unite, and is worthy our best consideration. Why not all of us urge it, and work the people up to its adoption. GLEANINGS can do much in this line. I do not see how this plan can fail of general support, and I am glad to urge it in season and out of season.

A. J. COOK.

Agricultural College, Mich.

Friend Cook, I am glad to know that you are deeply anxious in regard to this matter that lies so heavily on the hearts of our best people; and the greatest cause for anxiety now seems to me is, that people's convictions differ so much on what is best to be done. Many of our best Christians are positive that a certain course is exactly the course, and that no other can be right, while I find those who seem to be equally honest and earnest feel just as strongly that it is *not* the best way nor the right way. Many of the readers of GLEANINGS will feel hurt, no doubt, at some things in your kind article above (please turn to Our Homes for July 15th, 1883), while many others will rejoice to know that you have decided just as they have decided. Now, even if we can not think alike, let us try to have charity and kind feeling toward each other; and let us always be open to conviction. At one time during our civil war, when General Grant was pushing ahead, even though disaster and loss of life resulted, as it seemed, continually, many of our best and wisest people thought he ought to be stopped; and even his friends began to tremble for the consequences. Who was right and who was wrong? began to be the terrible question to meet. Who shall dare to take such awful responsibilities in matters where such terrible consequences are constantly following? Who should decide when none but God could know the outcome? Grant was allowed to go on, and it eventually transpired that he was wiser than all of us. He knew exactly what he wanted to do, and he did it. May God help us now in this present crisis.—I am very, very thankful to you for the encouraging words you have given GLEANINGS. What little I have been able to accomplish I never could have done had it not been for the kind and earnest support and encouraging words from God-fearing friends like yourself.

BEE DIARRHŒA: WHAT DO WE KNOW ABOUT IT?

MAY IT BE THE FAULT OF THE QUEEN AND NOT THE BEES?

FOR the past three or four years I have been of the opinion, that if our bees could fly every two weeks or oftener we should never know of such a thing as bee-diarrhœa; and while I am of the same opinion still, as far as our losing large apiaries is concerned (with the above conditions present), yet I have had an experience the past fall and this winter which shows that bees can have the bee-diarrhœa when they have a chance to fly often. This experience also points toward the trouble being caused by the queen, and wholly upsets nearly if not quite all of the theories which have been advanced regarding this dreaded disease of the bees.

The fore part of September, 1885, I commenced to prepare my bees for winter by looking each one over carefully, taking out the frames to see if they had honey enough, and to know their condition generally, as I gave on page 731. In this way I prepared a few colonies a day, along as I had time from my other cares, so that I did not fully complete the job till October 15. In thus preparing them I found that only 5 out of the 95 colonies had any brood in their hives, four of which had young queens which began to lay about Sept. 25th, the colonies of which were formed by uniting several nuclei together, and one other which was the colony which cast the third prime swarm of the season; consequently it had one of the first queens reared during 1885, as the colony was allowed to rear its own queen. This last-named colony happened to be one of the 15 last gotten ready for winter, and was prepared on Oct. 12th. At this time I noticed a little patch of brood in one comb about as large as a silver dollar, which looked similar to the first brood started by a colony in the spring. The queen looked rather larger than the other queens in the yard, and more as a queen does in early spring. They had plenty of well-ripened basswood honey, and a fair amount of pollen. A few days after this the hive was packed for winter, as were the most of the rest of them at that time. From the 20th to the 31st of October, all my bees had three or four flights, as they also did on one or two occasions in November, at which time those colonies formed by uniting nuclei, which had brood in them, carried in pollen from the witch-hazel quite freely; but from long-continued watching I failed to see a bee carrying pollen into the hive above mentioned. Instead of this they acted as nearly all colonies of Italian bees do in early spring; *i. e.*, they were standing thickly about the entrance, with many bees flying; those not flying were acting as if they were trying to guard the hive from robbers. As it came late in November I would see them flying upon days when not a bee would be stirring from any other hive, and now they began to show outward signs of diarrhœa, as they would spot the tops of the hives about them in their flights.

I was resolved, that if a day occurred that was warm enough to handle bees I would open this hive and see what I could learn regarding them; but so far there has been but one day on which this could be done, and that was when I was at Detroit at the bee convention. The day before Christmas they flew some, with the mercury at 44°, but I did not think it best to open them when so cool. The next day after I got back from Detroit I raised the hive from the bottom-board and found several immature young bees, all of worker size, on the bottom-board, at which time I cleared off all the debris found. At that time the hive seemed filled with bees, some of which flew out while I was cleaning the bottom-board, spotting the snow, and soon dying, as all bees do when they have the diarrhœa, and can get out. I have again this morning cleared the bottom-board, getting about a quart of dead diarrhœtic bees, together with quite a number of immature bees, the most of which are now dwarf drones. There was also a large quantity of as nice white wax scales fallen to the bottom with these dead bees, said scales being as perfect as any I ever saw in July. The bees, instead of occupying the whole hive, are now reduced so that they are between only five combs, occupying four spaces. Those on the outside of the cluster (if they can be said to be clustered) are bloated to nearly bursting, while the combs and surroundings are soiled, and smell as badly as do such hives having had diseased colonies in them, and dying in March. In fact, to-day, Jan. 1, 1886, they are in the last stages of bee-diarrhœa, which disease, it is evident, began about Oct. 1, when that little patch of brood was started. Now, what caused it? Did the queen and bees know that she was to become a drone-layer, and thus try to rear brood out of season so as to get a new queen? Or what did that desire for brood spring from? Surely it was not cold nor confinement nor dampness, nor their being obliged to eat pollen, nor any of the many causes heretofore given as producing said disease. Perhaps friend W. F. Clarke, of Canada, will say it was lack of hibernating. Well, perhaps it was; for all the other 94 colonies, both in the cellar and outdoors, even to the four colonies made of united nuclei, are in that quiescent state Mr. Clarke calls "hibernation."

Borodino, N. Y. G. M. DOOLITTLE.

Friend D., this matter was discussed some years ago, you may remember, and the thought brought prominently forward then was, that it so often happens a colony will winter all right, year after year, so long as the old queen lives; but when a new one takes her place, then we have losses in wintering. Almost every bee-keeper has had particular hives that always wintered nicely, and gave a good yield of honey, and large increase in bees, until the queen was changed or superseded, and then troubles came. I have been strongly of the opinion for some time that queens sometimes have much to do with this matter; at other times the peculiar good qualities of a set of combs seem to have something to do with it; and, again, the location of the hive, where wintered outdoors — its protection from the prevailing winds, etc., has seemed a factor. I am glad you have called attention to the matter of the queen in regard to this matter of dysentery, for may be there is more there than we have suspected. You know the "nameless disease" is often cured by exchanging queens.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

WORSE AND WORSE; BUT, GREAT IS TRUTH, AND WILL PREVAIL.

WE copy the following from the Chicago *Advance* of Dec. 31, 1885. You will notice that it is not hearsay, but something from the editor's own personal experience.

Pliny, the historian, laments that in his degenerate times men had learned to imitate realities and practice frauds upon the people. In proof of this he mentions a case in which Egyptian priests, who understood the natural sciences better, perhaps, than any others in the world at that time, had palmed off on the public counterfeit precious stones. They had learned to color glass, and take stones of varied values and cement them so that the untrained eye could not distinguish the combination from real gems. But what would Pliny think if he lived to-day and found what progress had been made in the art of imitation? We have laws against counterfeiting money, but none against adulterating food. I believe that thousands of people every year are seriously injured, if not killed, by the use of impure food.

I have recently had some personal experience in this matter. I tried in vain to get pure butter at prominent groceries in this city. It was oleomargarine, or something else, every time. Then I sent to the country, and procured some real butter from a family that I knew, but when it came it was artificially colored and wholly unpalatable. At last by writing to the interior of Iowa to a personal acquaintance I succeeded in getting pure butter. The time was, until recently, that if one got honey in the comb, he was sure about it. But all that is changed. Men have learned not only to manufacture the comb much more rapidly and cheaply than the bees can do it, but now fill it, capping the so-called honey cells by machinery, and sell it at a lower figure than any at which the real honey can be produced. Some of our readers know unscrupulous men in the country who having bought a few hives of bees, almost immediately began selling great quantities of honey in the comb. They procured it from the manufacturers of the adulterated article, but any one familiar with the taste of the real honey easily detects the fraud. I went to one grocer in this city, who had recently purchased, from Ohio, a thousand pounds of what he honestly supposed real honey, and convinced him in five minutes that almost the entire quantity was made up of syrups, deftly secured in the comb. He simply said, "What are we coming to?" We have no State laws sufficiently guarded in their provisions to reach these rascals, and punish them as they deserve. It may be permissible to manufacture the stuff called oleomargarine, or butterine, but to sell either as butter should be made a criminal offense and punished accordingly.

One of the most unique cases of adulteration that has yet been mentioned is reported from New Jersey, where a man was arrested a few days ago for selling false eggs. The shell was made of some translucent substance; the white of an albuminous preparation, and the yolk of saffron and carrot. Strangest of all, they made a very good omelet. The fraud was detected only when they were boiled. The ingenious manufacturer exhibited his wares to a New York dealer, and declared that they could be made on a large scale for half a cent apiece, while real eggs cost from three to four cents. I should think these conspirators would be ashamed to look an honest hen in the face.

You will notice that the editor goes back to Pliny, and laments the degenerate times. He does not tell what he has heard, nor does he copy from other papers, but he tells his own personal experience. In regard to the butter part of his story, I will leave that to the dairy people and dairy journals; but, Mr. Editor of the *Advance*, we beg leave to inform you that men have *not* learned to manufacture comb, and fill it with honey or any substitute.

If you have a desire to be fair and just (and the editor of a Christian journal certainly should have), we ask you to give us the name and address of the grocer who purchased that thousand pounds of honey from Ohio, that we may correct him as well as yourself; and when you give satisfactory proof that that comb honey was manufactured that you saw, we will pay you $1000 for the information. In behalf of the State of Ohio I also call upon you to give the name of the man from whom that honey was purchased.

"What are we coming to?" surely. In regard to your wind-up on the egg business, we beg leave to submit to you the article in our last issue on this matter. Now, if you refuse to notice this, or to do simple justice to a large class of people whom you have injured by your statements, we, as a body of bee-keepers, refuse to subscribe to your paper; and we call upon Christian people in general to aid us in bringing about justice. We are thus vehement in the matter, because, month after month, agricultural and religious papers persist in publishing such damaging false statements; and not only that, they almost without exception refuse to correct the mischief they have done. The *Rural New-Yorker* and *Prairie Farmer* have given us a hearing; but the rest of the press, at present writing, seem almost wholly given over to persistent falsehood. They remind us of the text, "He, that being often reproved hardeneth his neck, shall suddenly be destroyed, and that without remedy." and I have not a bit of doubt but that the warning in the text will be ultimately fulfilled. No doubt the man who manufactured (?) artificial eggs will be ashamed to look an "honest hen" in the face; but, how about the editors who get up these stories?

Since the above was written, Ernest has returned from New York. Among his wife's relations is an inspector, appointed by the State of New York, to look up artificial butter, or oleomargarine. This State inspector visits the restaurants and groceries in the city of New York. He does not tell them who he is—goes into a restaurant as anybody does. Whenever "oleo" is given him for butter, the proprietor is punished according to law. Well, how much do you suppose he has found that was not butter? comparatively little—at any rate by no means such a large amount as the newspapers state. Very likely you will say he is bribed; but, dear friends, we happen to *know better*. Now, of course, I do not know about butter as I do about honey and—eggs; but I will submit to your own good sense, readers of GLEANINGS, is it not quite probable that the editor of the *Witness* tasted some poor butter, and jumped to the conclusion that it was manufactured? By the way, another fact has come out in regard to artificial honey. A good many have been calling poor dark honey in the combs, especially where it had a disagreeable flavor, manufactured "stuff." Most of the readers have had some experience in honey-dew stored in combs, and know to their sorrow that it is *stuff*, without question, but not manufactured, by any means. If one were going to manufacture honey he would probably have something a good deal better than a good deal of the bug-juice that the bees have gathered and put into combs. I beg pardon for using the term "bug-juice," but nothing else would fit under the circumstances.

A SLEIGH-RIDE OF 150 MILES.

From 400 to 850, and Over 20 Tons of Comb Honey.

PURSUIT OF BEE-KNOWLEDGE, AND THE RESULT.

DURING the last week of March, 1885, the sleighing being excellent and the weather fine, and having business near Rutland, Vt., 40 miles from my home, I resolved to perform the journey with my little black pony "Nig." The journey was easily and safely made; and the next day at 3 o'clock, my errand having been accomplished, I called for a map of Vermont, and sought out the location of Bristol, the home of A. E. Manum. I found I should have to travel about 35 miles further to reach that highly favored place. At 8:30 in the evening, Nig had put 23 miles under her feet, and we found ourselves at the Addison House, in Middlebury, Vt.

While entering the State of Vermont from New York, one would think, from the nature of the view before him, that very hilly roads were to be encountered; but an agreeable disappointment is in store for the traveler. The roads follow up the streams; and though there are rugged mountains upon each side, the road is comparatively level; and as we pursue our winding way the scenery is ever shifting, showing us beautiful and romantic views, and which occasionally reach the point of grandeur.

From Rutland we follow up the Otter-Creek Valley; and from the amount of dairying and stock-raising that is carried on here I should judge it to be a good honey locality; and from appearances there are many locations that are not occupied with bees. There is much alsike clover raised upon these low meadows, and an abundance of basswood upon the mountains.

Learning that J. E. Crane, one of the great bee-men of Vermont, had moved to Middlebury, I soon found him and had a brief visit with him. At that time Mr. C. had about 800 swarms, in several apiaries. It is needless to say that Mr. C.'s yield of box honey is many tons. Mr. C. occupies a new house, which is a model of taste, and, I suppose, so fair an exterior must have a convenient interior.

A ride of 12 miles from Middlebury brought me to my objective point, Bristol. This little manufacturing village nestles snugly in a notch in the famous Green Mountains; a considerable stream tumbles through here, and gives power to several manufactories for working up wood. Among these is Mr. Manum's manufactory of bee-hives, and the famous white-poplar section. The manufacture of these is now conducted by Messrs. Drake & Smith. I found Mr. M., as we should find all bee-men who count their colonies by the hundreds, busily engaged in preparing for the coming season. I told Mr. M. that the object of my journey of 75 miles was to learn, if possible, how to winter bees.

After looking over the factory we adjourned to his residence, where is located his home apiary. At the time of my visit Mr. M. had about 400 swarms, in several apiaries. The well-known Bristol hive is used. This and the N. E. hive, manufactured by H. D. Davis, are very similar, and are largely and successfully used throughout the N. E. States for wintering outdoors. The packing used by Mr. M. is poplar shavings. The peculiarity of this wood is the amount of water it will absorb, and the shavings will absorb much moisture, and not become damp. We examined several hives, digging down through the loose shavings, and turning back the quilt. We found the hives full of bees, and very lively. The entrance to this hive is from the under side toward the center, and nearly all dead bees soon find their way to the ground. I think the hive would answer for W. F. Clarke to try his hibernating theory with. Mr. M.'s method is to leave a portion of honey *and pollen*. These frames of honey are all placed at one side of the hive. If there is any brood it is placed at the other side, and empty combs inserted, and the bees are fed up on granulated sugar. The stores are in such shape that the sugar is mostly consumed through the winter, while the honey and pollen are consumed in the spring. Mr. M. claims that honey is far better than sugar for stimulating brood-rearing in the spring. Not only the method of preparing for winter, but the hardiness of the bees, is of importance; and Mr. M. claims to have bred that good quality; and if we are to judge from his successful wintering of them, he has attained success in that direction. His yields of honey have also been remarkable. The 400 swarms in the spring increased to 850, and a yield of upward of 20 tons of comb honey, I believe, has been obtained. One swarm on scales gained 91½ lbs. in three days—30, 30¼, 31, during basswood bloom.

Mr. M. has many appliances of his own invention. His appliance for reversing frames is simpler and better than any thing I have ever seen. It is simply a piece of hoop iron, one end bent to form a projection and hook; the other end is provided with a hole by which it can be attached to the middle of the end-piece of a frame. A small notch is sawed in the frame for the hook to catch into.

I could spend but a few hours with Mr. M., and at 4 o'clock Nig and I were on our way back to Middlebury. The next day we got over the distance of 50 miles through another portion of the State, and parallel with Lake Champlain. We passed several apiaries of Bristol hives, and longed to call upon the owners; but the beautiful snow was wasting, and we had to speed homeward or encounter much bare ground. After passing the night in Whitehall, an easy drive put us home again.

As a result of the trip, I am wintering 100 swarms of bees outdoors, not in Manum hives, but packed very similar to them, and fed to a certain extent on granulated sugar. I also have nearly 100 in the cellar. Should any one desire a more full description of Mr. M.'s method they will find an article from his pen in Alley's Handy Book, latest edition.

Hartford, N. Y., Dec. 31, 1885. J. H. MARTIN.

I am sure, friend M., we are very much

obliged to you for your vivid account of your profitable visit. At the Detroit convention a pleasant-looking man came up and said he wanted to shake hands with his benefactor, or something of that sort. I asked him what he meant by that, and he said he was A. E. Manum, and asked me if I remembered the time I advised everybody to send for a sample of his white-poplar sections. I told him I ought to remember it, because it was a pretty hard struggle with conscience before I decided to admit that somebody else was making better goods than I was, and to advise the friends to send there for them. He said my notice so overwhelmed him with orders that it gave him his first start in business, and enabled him to build up such an apiary as friend Martin tells us about.—Over twenty tons of comb honey as the product of a single season! Just think of it!—In regard to the reversing device used by friend M., I will explain that it is quite similar to our own, only that it is made of a strip of heavy hoop iron; and the last end, where it comes up over the top-bar, is turned straight downward, and snaps into a saw-cut made at the proper place across the top-bar to the frame. This device was submitted to us some time last summer, but we can not remember now who sent it.

DISTURBING BEES IN CELLARS.

FACTS AND SUGGESTIONS FROM C. C. MILLER.

I CAN not believe it is a good thing for bees to be disturbed in winter, and yet I am obliged to confess it is by no means so harmful as I formerly thought. One winter I had a hive so placed that it got a pretty good kick about once a day. I could not see that it was any the worse for it.

LENGTH OF LIFE AFTER STINGING.

In trying to ascertain how long a bee will live after losing its sting, the experiments, so far as I recollect, have been faulty in one particular. The bee, after losing its sting, is caged or confined, and this alone would shorten its life. To make the experiment at all satisfactory, an uninjured bee should be confined along with the stingless one, and the difference in length of life noted. Care should be taken that the bees should not be injured in handling. I have many times seen so much of the viscera of the bee come away with the sting that I can hardly believe the bee could live very long; but I have a good many times been surprised to see bees that showed evident marks of having lost their sting, lively and bright in appearance, in colonies that I had no reason to believe had been in any way disturbed for a day or two, and no stinging going on at the time of my handling them. Of course, they *may* have stung some person or other bees, without my knowledge, but I am afraid we don't know much positively about this matter.

BAREHEADED BEES.

I have just been looking in A B C to find what Mr. Root says, but can't find it. I feel pretty sure, however, that somewhere he has said it is all right and proper to have young bees in cells nearly ready to hatch, with no capping over them. For several years I have had the impression that such things were not all right, and rather settled upon it that, when I found bareheaded bees to any extent in a hive, I wanted a new queen in that hive. I still lean in the same direction; but until the past summer I had no idea what was the immediate cause of the trouble. I *think* it is the wax-worm. Did you never notice that the bareheaded bees were more or less in rows, somewhat as you leave uncapped cells when digging out their galleries in search of worms? Another thing: Did you ever see any bareheaded or uncapped grubs older than the ordinary age for remaining uncapped, say about a week from the egg, and yet so young that the head of the young bee was not plainly formed? I don't think I ever did. Now, the young bee is ordinarily sealed up about 11 days; and if the bees leave them unsealed, we should be able to find them at all stages of development; but I never saw one unsealed presenting the appearance of a larva within two or three days after the time of sealing. Since writing the above I find this in A B C: "You can rest assured that the bees almost always know when it is safe to let the children's heads go uncovered." Now, I don't quite think they ever leave them uncovered, till the wax-worm uncovers them, or runs a gallery over the bees in the cells for the bees to dig away, thus leaving the cells uncovered. If the bees think it safe to leave some of them uncovered, why not in larger patches? and yet, did you ever see a patch so large that you could lay a silver dollar upon it, and have all the cells under it uncovered? Perhaps by observing next summer we can settle the matter.

COLOR OF POLLEN.

It is a thing of some interest, and at times may be of importance, to know the sources of pollen; and it would be a help in this direction if we knew the color of the different pollens. Suppose the juveniles, and elders too, for that matter, send in, next summer, lists of the different colors of the pollens they have observed by seeing the bees at work on the plants. From this, Ernest might make a pretty full table; and then if it were put in the A B C it could be referred to at any time. I will start by giving: Plantain, white; poppy, black (I think likely, however, the color of poppy pollen may vary with the color of the flower); burdock, I think it is white, but I'm not sure; then I was going to give white clover, brown; but I don't feel very sure without having it before me, showing pretty plainly that my powers of observation have not been as carefully educated as they should have been. For the young, this may be an important step in their education.

LENGTH AND CALIBER OF SUB-VENTILATING PIPE.

Perhaps we are not far out of the way in settling upon three or four feet as the best depth, all things considered, to lay tiles for sub-ventilation. Now, what is the best length, and what sized tile is best? The larger the pipe, the more air it will admit, but, at the same time, the colder it will be. The longer the pipe the warmer the air; but a pipe a mile long would probably not make the air much warmer than one 200 feet long. If one tube is made of four-inch tile, and another of six-inch, the six-inch one will admit more than twice as much air as the four-inch, but it would have to be longer to admit air as warm as the four-inch. If the cost of the tile be the main item of expense, then it may be best to have six or eight inch tile, and run it deep enough and far enough to secure the desired warmth. If labor is principally considered, it might be better to lay two four-inch pipes about a foot apart. This would require only one trench to be dug, and give warmer air than if larger tile were used. I wonder if we can get answers to these questions: What sized tile is best, in general, to use? When laid, say four feet deep, how long a pipe of six-inch tile will admit air of same temperature as 150 feet of four-inch tile? My sub-ventilating pipe is of four-inch tile, laid three to four feet deep.

C. C. MILLER, 179—340.

Marengo, Ill., Dec. 28, 1885.

After I had written my reply to Nettie Cranston, page 70, we received the above communication from you. You observe that I took the same ground; namely, that we are liable to err in supposing that bees *invariably* die after losing their sting. Since your opinion confirms what I have read somewhere, I feel better satisfied that a bee *may* live a number of days after the loss it has sustained; but I do not see why caging on the Good candy necessarily hastens the death of an injured bee when the latter, according to the reports so far, survive not more than 20 hours, and a perfectly sound bee, with similar treatment, lives on an average a week or ten days.

If any one by actual observation knows of a case in which a bee deprived of its sting lived and gathered honey, let us have it. I have seen instances that led me to suppose that such might be true, but I never could fully convince myself.

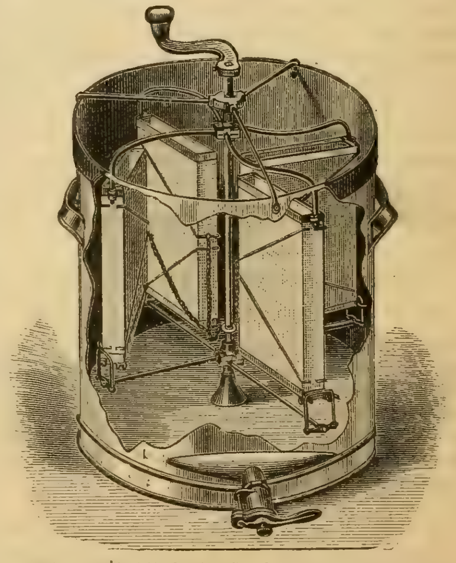
Thanks for your suggestion in regard to the color of the pollen; but a juvenile has already anticipated your idea, as you will see, page 872, last year. You notice the little girl has given the color of pollen from quite a variety of flowers. When the weather opens up I intend to get the juveniles to make a collection of pollen, nicely arranged on a card, much in the way that bugs and geological specimens are gotten up. The sources of the pollen are, of course, to be plainly written below the specimen. With a collection of this kind an inexperienced hand could easily tell what the bees were working on, providing the specimens were accurately named. ERNEST.

I feel sure, friend M., I have seen patches of bareheaded bees a good deal larger than a silver dollar; but it is so many years since I have given the matter very much attention, I may be somewhat mistaken. I know we marked the combs, and the bees hatched out perfectly formed, and all right so far as we could observe. As to whether they were capped a spell and then afterward uncapped, I can not answer; but I suppose they had been, for I never noticed those uncovered until they were almost ready to hatch, fully formed, and partially turned dark. My impression is, the bees opened them for some reason best known to themselves. The openings are nicely arranged with a little edge turned up, something like cells just under the process of construction.—In regard to marking bees that have lost their sting, I would suggest putting a drop of white paint on their backs. This will enable us to hunt them out, even though they have the regular run of the hive.—In regard to sub-earth ventilating-pipes, you say yours is a four-inch tile laid three or four feet deep; but I can not find in either of your articles how long the pipe is. Please give us the length, and then we shall have something to start on.

STANLEY'S IMPROVED HONEY-EXTRACTOR.

A HONEY-EXTRACTOR TO REVERSE THE COMBS BY TURNING THE CRANK IN THE OPPOSITE DIRECTION.

OUR readers will recollect that we have described this machine before; but in the absence of a good engraving we could not give a very clear explanation. Our own engravers have, however, tried their hand on it, and give us the good picture shown below.



STANLEY'S AUTOMATIC HONEY-EXTRACTOR.

You will notice that the baskets to hold the combs are hung by a sort of hinge at the top, with a kind of double hinge at the bottom. This double hinge is after the plan a great many gate-hinges are made; viz., a double bearing, so the frame is thrown off to one side as it is pushed back either way, letting the force of gravity operate to bring it into position again. Well, around the shaft, toward the bottom, you will notice a little ring. Four chains are attached to this ring, with their other ends fastened to the swinging comb-baskets. Take hold of the crank and give a quick impulse, and the baskets, by "mutual consent," swing off their centers. As you continue to turn, centrifugal force would swing them against the side of the extractor were it not for the four chains just described. The little ring jumps up to about the middle of the shaft, and the four chains are drawn taut.

When you have extracted the honey from one side of the four combs, stop long enough for the baskets to commence swinging toward the center, then start up the other way, and they by common consent turn t'other side out. The machine works very prettily. We can furnish them at Stanley's prices, as given below:

The following is our list of prices for machines taking the L. frame, 9⅛x17⅝, outside measure:

2 frames	$12 00	4 frames	$21 00	8 frames	$40 00
3 "	16 00	6 "	30 00	10 "	50 00

The above prices are for machines with no gear, but with crank attached to the top of center-strips instead. We add a good strong horizontal gear for $1.00 extra, or our best vertical gear with crank at side of can for $2.00 extra.

If any size of frame is used except the L. frame, please mail us a sample frame in flat, and write, stating how many combs you want your machine to carry, and we will give you prices by return mail. Do not send measurements, trusting to that to have your baskets made, but always send a sample frame, as we absolutely refuse to make baskets for any other than the L. frame unless we have one of your frames to work by. *This rule must be observed in all cases*, and then we will guarantee our machines to work perfectly.

The machine is represented with a plain crank on top of the shaft, and for four combs I should most assuredly prefer it in that shape.

THE NAMELESS BEE-DISEASE.

SOME FACTS AND SUGGESTIONS IN REGARD TO IT.

LAST September I noticed one of my colonies acting strangely. The bees began dragging out others that were not yet dead, but acted as though they were partially paralyzed. They would lie on their sides, and their legs would keep constantly twitching. Sometimes a bee with its body greatly distended would rush out of the hive with its wings spread out and in constant motion, and hurry off into the grass, as though trying to escape from something in pursuit. The queen was a young one that had got mismated, and the colony had plenty of natural stores, for it had worked better than any colony I have. Thinking that the trouble might be in their stores, in November I gave them all the sugar syrup they would take, which was not much. I thought I could see some improvement, but it may have been a mistake.

January 5 was warm, so all the bees had a good fly. They are all in your chaff hives. A good many dead bees were drawn out of this colony, some looking as though their insides had been eaten out. I caught one that was largely distended, and fluttering off into the grass, and I put it under a microscope. Its body seemed to be filled to the point of bursting with a pale amber-colored fluid which appeared to have exuded in some way, and covered the body with a coat of varnish. The bee panted badly, and kept up a constant jerking motion with its legs. It died while I was examining it. Before it died it voided a perfectly white substance, hard and glistening, and afterward a hard amber-colored substance. I then took a dead bee just drawn out, and put it under the microscope, and found its body covered with the same thick varnish that had hardened, somewhat, and could be scraped off with my knife. I think these diseased bees burst open, and the others ate out the contents of their bodies; for in taking out the dead bees from time to time I have always found live ones in the bottom. Dr. Scranton, who lives near me, has some colonies troubled this way. Is this the "nameless disease"? A. POTTER.

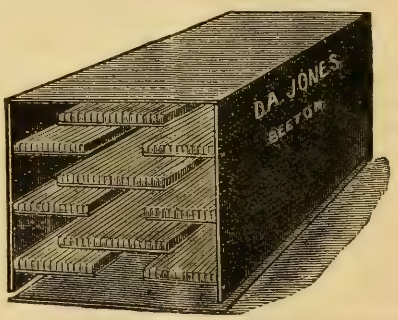
Bennington, Vt., Jan. 7, 1886.

Friend P., you have described the disease exactly, and it is this glutinous liquid, probably, that causes the shiny appearance of the black, emaciated bees as they creep out from the entrance of the hive.

JONES'S FEEDER.

D. A. JONES'S WINTER BEE-FEEDER; A FEEDER THAT WILL PROBABLY WINTER BEES WITHOUT ANY COMB.

AMONG a lot of other inventions brought to Detroit by our clever and liberal Bro. Jones was the above bee-feeder; and before describing it I want to say that the more credit is due friend J., from the fact that he has very little inducement to exhibit these things in the way of making sales, because of the duty. He shows us his inventions, explains to the fullest particular how they are to be made, and does not receive one copper, and no prospect of receiving any. It is solely his generous good will to the bee-keeping brethren.



FEEDER FOR FEEDING THE GOOD CANDY.

The arrangement is a little box about six inches square and a foot long. The sides are nailed into the ends; but before the box is nailed up, the ends have grooves plowed in them lengthwise, about an inch apart. These grooves are made about half way through the end-board; and sticks, ½ inch by ¼ inch, and as long as the end-board, slip into these grooves, projecting enough to hold the grooved shelves shown in the picture. These shelves are made by running strips, ½ inch thick, over a set of dovetailing saws, so as to give them the fluted appearance shown in the picture. The boards are of two widths, as you notice. Those against the sides are 2½ inches wide. The middle ones are 3½ inches. We copy the directions for use, and the prices, from the *C. B. J.* for November.

Take pure pulverized or granulated sugar—the former preferred—and stir it into honey, nicely warmed up, until the honey will not contain further additions. Allow it to stand in the dish until both are thoroughly mixed through each other, then place in feeders and set them on top of the frames, packing all around nicely to allow no heat to escape.

Each, made up,	.30
Per 10,	2.75
Each, in flat,	.20
Per 10,	1.75

D. A. JONES.

Our friends who live in Canada will, of course, get them from friend Jones; and those in the United States who would like to try them can have them at the above prices from our establishment.

A GOOD REPORT FROM TEXAS.

HONEY FROM THE BROOMWEED; FROM 70 TO 100, AND 10,000 LBS. OF HONEY.

WHEN giving you my report in Oct. GLEANINGS, page 679, I believed our honey crop to be all gathered; but since that time I have taken 2000 lbs. more from the same apiary, making a total of 6500 lbs. The above report is only from my home apiary, of which I began the season of 1885 with 70 swarms, and have increased to 100 by natural swarming. The last 2000 lbs. has been from broomweed alone, and is the first time it has yielded in the four years I have resided in Texas, and it is entirely different from any honey I have ever seen before. It has a peculiarity of becoming solid without granulating; in color it is white, with a yellow tinge, and will become solid in 24 hours if it is exposed to the cold.

On Christmas day, bees were making honey from the mistletoe, which is now in bloom.

My honey crop this season was over 10,000 lbs., and has netted me 8 cts. per lb. My plan of selling is to allow only one firm to handle my honey in each town or city, and to sell on its merits alone. One house has sold 2250 lbs. this season for me.

I have sold out my sheep interests, and next season I shall devote my time to bee-keeping; and if the season is good I shall try to make a good report.

I have a water-wheel for motive power to run my saws in cutting out hives. It is one of my own construction, and works finely. I shall use only the Simplicity hive, as for convenience in handling, cheapness, etc., I think it stands without an equal. Wishing you and GLEANINGS every success in the new year, I will close. WM. WRIGGLESWORTH.

Crawford, Texas, Dec. 28, 1885.

FRIEND CLARK'S TRIALS AND SUCCESSES.

FROM 4 TO 18, AND 200 LBS. OF HONEY.

I BEGAN to keep bees in the spring of 1878 by the purchase of one old box hive. I was fortunate enough shortly after to spy the advertisement of A. I. Root in some journal or other, and ever since I have been a very interested reader of GLEANINGS. I went through the A B C, Quinby's New Bee-keeping, and other such as I could get hold of, devouring the entire contents with a relish that would have done credit to a Doolittle or an A. I. Root; but I have never realized any great yields such as I read of, nor have I been able to number my colonies by the hundreds, but I have received a good fair return for all money and time spent, besides the pleasure and recreation, which were worth a great deal to me, for I have been afflicted with heart disease for the last seven years, and it has grown so serious of late years that I have not been able to do any hard work at all. To make things worse, my wife was taken down with fever at the birth of our little girl one year ago, and has never been able to rise from her bed. God only knows whether she ever will or not. It seems awful hard, but we believe all things work together for the best to those who love and serve the Master. But, to return. In the fall of 1884 I had 22 colonies, very heavy in natural stores, but it was honey-dew which hardened in the cells as fast as gathered, and could not be thrown out with the extractor. Having no empty combs to feed up on, I was compelled to let them take their chances, expecting the worst, and I wasn't disappointed; for 19 out of 22 died, and the three that were left were not able to cover one frame each. But I pulled them through, and bought one more. From the four I took 200 lbs. of section honey, and increased to 18, and one went to the woods. I doubled back to 14 in the fall, which have clover honey to winter on, so we feel comparatively safe for next season. Our honey was all sold at 25 cts. net. J. A. CLARK.

Summersville, Pa., Dec. 23, 1885.

A POSTAL-CARD LETTER, WITH SEVERAL MORALS TO IT.

SENDING FROM FLORIDA TO OHIO FOR QUEENS; TEMPERATURE OF WELLS IN FLORIDA, ETC.

FRIEND ROOT:—I thank you for your reply to my inquiry; but by accident (if accidents ever do happen) I found that a former member of your business family, Miss N. Adams, was engaged in bee-keeping about six miles from here, and from her I obtained the needed queens. In view of the experiments that Ernest has recently been conducting, it may be of interest to you to know that the temperature of water as it comes from wells in this part of Florida is about 70°, varying a trifle with the wells. Bees are gathering pollen nicely. Not much honey. The letter was written with a Hall type-writer, made by the Hall Type-writer Co., New York. C. H. LONGSTREET.

Mount Dora, Fla., Dec. 30, 1885.

Now, friends, you see that friend L., who writes the above, wrote us about queens; but by accident, or providentially, if that is a better word, he found out that one of our former pupils, Miss Adams, was raising queens for sale, within only six miles of his place. Just think of it! Very likely it would have been nothing very strange had we purchased queens of Miss Adams, had them shipped all the way from Florida clear up here to Medina, and then sent the same ones right back again to fill his order, when, had we known enough about each other, he could have got the queens within six miles of his home. I like to sell queens, and I like to sell any thing when I can benefit the purchaser as well as myself; but it does me a great deal more good to hear of some of our former employes taking our trade by doing the business in the way above mentioned; that is, where they can do it so much better and so much easier.—Why, friend L., if you do not have any water to drink out of your wells that is colder than 70 degrees, I am real sorry for you. Perhaps you have not got down deep enough. Can some one give us the figures from Florida on artesian wells, say several hundred or a thousand feet deep? May be I shall have to give up my pet theory, that the temperature of the earth is about the same, either north or south, when we get down deep enough.—Now in regard to the concluding sentence. The letters have been so very nicely written that I asked the writer what kind of a type-writer he used, and you have the name and address of the maker. I am sorry, however, that he did not tell us the price.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Dec. 15.

CHAPTER VII.

For dust thou art, and unto dust shalt thou return.—GEN. 3: 19.

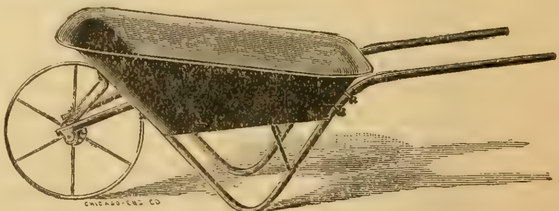
While on the cars on my way to New Orleans, nearly a year ago, I wrote something like this: "I have just made a great invention." The above was put into an article for GLEANINGS; and as months passed and nothing further was said in regard to the matter, several of the friends inquired, "What about the 'great invention'?" Well, the reason why I delayed giving further particulars was because it is a rather delicate subject to handle; and I do not know now but that some of my good friends will turn away in disgust from what I have to say in regard to a matter that seems to me is one of the great matters before the people of the present age. My thought was directed into this channel by the imperfect arrangements on many of our best railroads for the accommodation of the traveling public in the way of water-closets. On my return from New Orleans, while occupying a beautiful cushioned seat in one of the best palace cars, I was suddenly surprised and annoyed by a most intense steaming-up of foul odors. At first I looked at my fellow-passengers suspiciously. Then I noticed that my seat was not very far away from the closet. And this was in a palace car that cost an immense sum of money. The makers had taken every pains, and gone to great expense, in order to have these things fit for cultured and intelligent people. In some of our hotels we have found much the same state of affairs. It has seemed to me that this is the great unsolved problem of the age. Princely hotels, steamboats, palace cars, schools and colleges, expositions, and other places where people of intelligence and culture do congregate, have been planned and devised in vain. Money has been expended lavishly, but only to meet disappointment, and oftentimes disgust. One great difficulty in this matter is the stubbornness of humanity. People will be — I dislike to say it; but, to come right down to the plain truth, the word to be used is—*nasty*. Even well-bred people, or at least those whom we should expect to be well bred, and to be neat and orderly in their habits, look on and see how money has been expended, and how carefully the plans have been laid to make these necessary places o they can be easily kept sweet and clean, but they don't care.

The most *perfectly awful* place of the kind I ever saw anywhere in my life was at the Ohio State Fair. I know it is not in good taste to complain and find fault, but I know there are others like myself who feel almost desperate about the way this matter stands. When I meet the great minds of our age; when I hear them talk at our conventions; when I witness what mind has succeeded in accomplishing with inert matter and nature's forces, I feel as if man were created in God's own image; and when I meet good earnest Christian people, I feel strongly that there is a God part in us all, as well as a remnant of a savage and animal nature. At such times I feel proud of my fellow-men; but when I over and over again meet such sights as I have hinted at, if I have not described them, a kind of feeling comes over me that man is largely animal still, and an animal, too, of which some of the four-footed dumb brutes might be ashamed.

When I call attention to these things I am met with the remark, "Well, what is a body to do?" or, "I do not see that there is any thing to do but to put up with it as the rest do." Probably the bad state of affairs comes about as it does at our country schoolhouses (or, if you choose, our town and city schoolhouses). Somebody goes a little way in transgressing the rules of neatness and propriety, and the next one thinks that, as that seems to be the fashion, there is no way but to follow suit; and probably, without intending it, he is a little worse than his predecessor, and pretty soon all scruple is trampled under foot, and then we have sights that *are* just awful. Our sweet, clean, well-dressed little boys and girls are forced to see sights that pretty soon break down all that a fond mother has accomplished at home in the way of instilling into the little minds a love for cleanliness, order, and purity. I hope this state of affairs is not universal. I can not bear to think it is. And, by the way, if any of my readers know of a schoolhouse, college, or academy, where they have something to be proud of in this direction, and keep it up month after month and year after year, whenever I come that way please ask me to come and see it. I know there are private homes where these things are managed nicely, and even where money is not plentiful, as well as among the rich; and I have many times inwardly thanked God for these exceptions. One case of this kind comes to my mind now. It was a minister's home. His salary was not large, and the good wife was obliged to do her own work, even though three little ones claimed her as their mamma. But these little ones evidently took as much pride as their mamma did, in being careful and cleanly in all their habits, and in making the best of such accommodations as were to be found in a *rented* home, and quite an humble one at that.

Well, how about that invention? Why, it was an invention in this line that made me pencil down, while riding in the cars, that I had "just made a great invention." I felt sure then that it was, and I feel sure yet. It would prove so, could humanity be made or induced to fall in with the end to be accomplished. When I got home I submitted the matter to my wife, before putting it in print, and she pointed out objections that I had overlooked, so I reluctantly kept still about it; but now I will tell it to you, for it is going to be a factor or step, perhaps, in getting at something which I think is a real improvement.

No doubt many of you will ask what is the matter with the dry-dust arrangement—such a one as I mentioned finding at the Agricultural College in Michigan. Well, in the first place, even if the dry dust will work splendidly year after year in such a home as Prof. Cook's, or where you have only intelligent and cultured people, yet years have passed since this was fully explained, and I have not yet found a *public place* where it was adopted. The traveling public would laugh at you, probably, if you should suggest the idea. They are too impatient, too much in a hurry, and too selfish, perhaps, to bother themselves over any such matters. The universal system in vogue everywhere seems to be by the use of water, washing away the offensive matter as quickly as possible; and where the traveling public will not take any pains to operate the simple machinery, a hired janitor keeps an eye on the apartment, and keeps every thing in nice order. I presume one of the most difficult points of the problem is to get a faithful *hired janitor*. I judge it is difficult, because I have heard hotel proprietors severely upbraiding the janitor because he did not keep things more orderly and sweeter-smelling. I have also heard the sleeping-car conductors reproving the porters with terrible oaths, because the porters neglected their regular appointed work. And it is not only the public places where these things are neglected, but it is in private and humble homes as well. Dear reader, I hope you will not be offended if I ask, if it is not true that *you* have, at some time in your life at least, failed to care for these outbuildings as they ought to be cared for. As a rule, I believe our wives have done their part faithfully; and sometimes when they call attention to the matter, when urgent business is crowding, I am afraid we men-folks get a little cross and impatient. Well, in considering these things, and in considering, also, the well-known fact that the contents of these outbuildings make an excellent fertilizer for the garden, I decided on my plan while riding on the cars. The plan was, briefly, this: I would have this necessary outbuilding made much as it is now; but instead of being *under* ground I would have it *on top* of the ground, and have it raised up high enough so that, by opening a door on the back side, or such side as is most cut off from view, an all-metal wheelbarrow, such as we picture below, can be pushed under so that the metal box would come in the right position to be loaded up automatically.



ALL-METAL WHEELBARROW.

Of course, a good layer of dry dust is to be placed on the barrow, and a barrel or box full in a convenient place, and each member of the family carefully instructed in regard to the use of this dry dust. When the wheelbarrow is sufficiently full it is simply pulled out and run out to the garden, and the contents spaded into the plat of ground that needs enriching. If the good man of the household is an enthusiastic gardener or fruit-grower, no doubt the plan would work nicely. The wheelbarrow, as you will notice, is all metal. There is not a particle of wood about it. If it should get soiled, however, or if wanted for other purposes, it can be quickly cleansed with boiling water. One objection to the plan is the expense of such a wheelbarrow. It is, I believe, about $7.00. Another is, it is such a splendid implement to have around for a hundred different purposes, that it could not well be spared for my sanitary arrangement. You might say, then, that two wheelbarrows should be procured, keeping one for this express purpose. But even $7.00 would be pretty expensive for a good many of us—or, rather, the interest on $7.00, year after year. Another objection to the dry-dust arrangement (and this is the one my wife emphasized) is, that the children will manage to raise a cloud of dust, be they never so well taught. Then the outbuilding must be *dusted* as well as *washed*, or, first you know, your Sunday clothing will show dust-marks. Dust is easily brushed off, it is true; but it takes time to go after the clothes-brush, and then put it away exactly where you found it. Besides, you might not notice the dust, and therefore unconsciously appear among respectable people with more "dust of the earth" visible on your outer person than is desirable. And that reminds me of my text at the head of this chapter. We are made of dust, and to dust we must return; and in regard to disposing of the contents of our closets and outbuildings, I am firmly persuaded that the only right plan is to restore this troublesome accumulation right back to mother earth, whence it came. It came from the dust of the earth, and it must ultimately go back there.

I wonder if it occurred to any of you while reading Chapter V., about "The Waters Led Captive," that friend Cole was, whether he knew it or not, opening up an avenue (I guess avenue is the word, is it not?) for the disposal, not only of the sewage and soapsuds from our kitchens and laundries, but also for the disposal of the contents of these outbuildings of which I have been talking. After I had studied the matter over a little it came into my mind that we had arrived to at least one happy solution of a great part of these troubles, and I wrote to him about it. Here is his reply:

HOME ON THE HILLSIDE,
Wellsville, N. Y., Dec. 5, 1885.

Friend Root:—

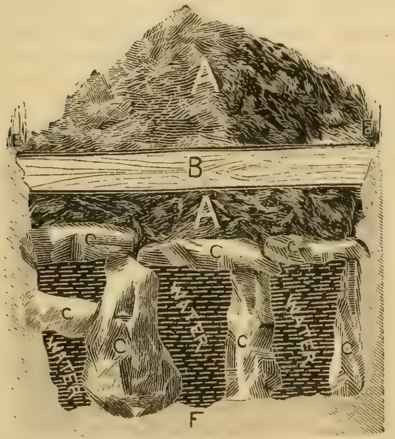
As regards the privy-vault, my own methods tell the story. At the termination of my reservoir trenches above my house, are three successive wells, at different levels, with overflows. These are severally five, six, and eight feet deep, filled with round stone up to the overflow, and as perfectly shingled, sodded, capped, and sealed with clay, with surface soil finishing up, as can be well conceived. The water falls into the first, and passes through filters in succession, till from the last, near the bottom, there issues from a pipe an inch stream of water, as fine as the best in the world, *a flowing well*, which supplies the household, and waters all of our horses, cows, etc. (not a large number, but of sufficient intelligence to refuse to drink from any other fountain). The bore of the pipe being only an inch, the water rises in the well and overflows, running down, passing in constant stream through our privy-vault, and liquidating the solids; the stream moves on into a deep trench across the garden, from which, overflowing through filters, and flowing through surface and percolating through subsoil, my spring brook is reached, the water being perfectly clarified.

Next spring I begin work to drop all surface washings about the barns, sty, hen-house, etc., into trenches, saving all liquids and solids operating as food for plants, and filtering and completely purifying all waters. The rains, dews, and snows are all run through the soil, nor are any at all seen upon the surface; and to this complexion will it come at last, when ushered in shall be the new heaven and the new earth, with their good time coming. I shall see only its advent here, but shall go where it has been already realized, and I am content. Hoping to meet you there, if not here, I am very truly your friend, A. N. COLE.

You will notice that friend Cole has almost unconsciously, as it were, accepted the present condition of things, admitting that the plan followed by most of our institutions is the most feasible plan; viz., using water as a means of cleansing these places. Heretofore the question has been, What shall we do with these washings, and sewage in general? I do not know exactly how large cities dispose of their sewage; but, I believe, as a rule it is run into the rivers, lakes, or ocean. The town of Pullman, in Illinois, has set an example by utilizing the sewage of that city for raising vegetables; but I do not know how it is distributed among the growing plants—probably by a system of pipes under ground. If any of our readers can give me any more information in regard to the matter, I shall be very glad of it.

I will now tell you what we have already done in this matter at the Home of the Honey-Bees. In accordance with friend Cole's instructions I have dug a system of underground reservoirs. We did it during the mild weather in the latter part of December and first of January. The engraving on the next page will make it plain to you how we constructed them.

Perhaps I should preface my explanation by saying that stone is so scarce on our ground we are obliged to purchase broken fragments from the quarries at $2.00 a carload, as I have mentioned before. Well, although the stone costs only $2.00, the freight on the carload was $9.00, making in all, perhaps, a dollar for a good two-horse wagonload of broken stone. Now, as the purpose of our reservoirs was to get as much room for water as possible, at the same time using as little stone as possible, we placed them as figured in the cut, so as to make interstices, or water-passages. C, C, represent the stones; A, the earth; B, a board put in temporarily to keep the bank from caving into the last-made pit. In practice we use two such boards, 14 or 15 inches wide. The ends are let into the bank so that they will keep the dirt from caving in when the dirt is thrown in on the front; when they are no longer needed they are pried out with a pick, and moved along to the next excavation. F is the solid earth before being dug.



AN UNDERGROUND RESERVOIR, CONSTRUCTED FOR THE "NEW AGRICULTURE."

In accordance with friend Cole's instructions, I made my first two reservoirs, along the highest part of our garden, between five and six feet deep, and six feet in width. The main reservoir is about 150 feet long; but as the ground is not quite level, in order to get the bottom to a water-level we dug down six feet on the highest ground, and about four feet on the lowest. To avoid handling this great amount of earth more than once, we proceeded as follows: We made a wooden frame six feet wide and eight feet long. This frame was laid on the ground at the place of starting, and then with a spade we cut all around it. The frame was then moved away, and the earth dug out with spade and shovel and pick, and thrown on three sides of the excavation. After it was all dug out, stone were placed in, as shown in the cut, to the depth of 2½ feet. On top of the stone we threw tin scrap from our tin-shops, broken glass and crockery—any sort of rubbish we wanted to dispose of, to be found anywhere on the premises. Old tinware was also used to take the place of the stone; old stove-pipes and sheet iron—any thing that was lumbering up the premises, being sure to place it so the weight of the earth above would never crush it down into the water. After the tin scrap, etc., we put on scraps of leather, old boots and shoes; lastly, coarse manure for two or three inches. Now, instead of throwing the earth back into this pit from the sides, we took the outline frame used before, and made another excavation south of the first one, the dirt being thrown from the first to the north end and on the east and west sides. Perhaps I should explain, that our ground has ordinarily from six inches to a foot of vegetable mold on top. Underneath this is a subsoil of yellow clay. I was inclined to think that this yellow clay should be carried away; but friend Cole says not. Now, let A represent the bank of earth on the north side. The one foot of vegetable mold, or good dark-colored soil, was spaded out; but instead of throwing it out on the stone covering, we pitched it on A. When it was all off so as to leave nothing but yellow earth in the second pit, this yellow earth was pitched on to the manure covering the stones, throwing first a few inches of yellow earth, and then a few inches of manure, so that the contents of the pit above the stone was manure and this yellow subsoil, about half and half. Loads of manure had been previously piled on each side of the path of this reservoir. You will observe that the trench was carried along in this manner, putting the good soil on top of the banked earth at A.

Well, after this reservoir had been carried about 75 feet southward, it passed close beside one of the outbuildings belonging to the factory; but the covered reservoir was at such depth in the ground that the top of the stones was still a little lower than the bottom of the vault of this outbuilding; so you will see all that was needed was to make an inclined plane under the outbuilding so as to permit the contents to be easily washed by the water into the reservoir. When this was done, the garden soil was nicely banked all around this outbuilding, making it warm enough so a zero freeze would not at all affect the contents. Who has not been annoyed during zero weather by a freezing-up of the contents of these outbuildings? Perhaps I should here state, that during a very severe shower of rain, or when the snows melt in the winter, we have a flood of water coming on the west side of our garden. I have laid underdrains with large-sized tile repeatedly, but still quite a freshet sends a little flood down among our honey-plants and flowers. Well, before finishing up the piece of work I have been describing, we constructed open ditches on the west side of the garden, to connect with large-sized tile so as to empty all the water, from the west, under this outbuilding, so you see the effect of a rain will be to wash the contents into my large underground reservoir, where the roots of our plants and trees can help themselves. If you look at friend Cole's letter you will notice that in the last paragraph he suggests an arrangement whereby our poultry-houses, pig-sties, and even stables, may be so arranged as to allow the contents to either drop directly into one of these reservoirs, or so they can be washed in with very little pains. Liquid manure and all, is thus quickly and almost automatically sent to the fields to fertilize growing plants. Instead of laborious carting and teaming, and then more laborious plowing and harrowing to get these substances into the soil, the rains are taught to do this disagreeable and laborious work. May be you will think friend Cole and I are borrowing from our imagination somewhat; but I think every candid reasoner will allow that friend Cole has accomplished a great deal, any way, even if it should transpire that *all* he proposes to do may not be secured.

In connection with this matter of outbuildings, there is another thing I want to be excused for calling attention to. Many such buildings are so arranged, or made so loose with joints and cracks above and below, that in the winter time there is great danger of delicate people, women and children, taking cold by cold drafts and exposure. When it is nicely banked up as I have described, and made close and tight, no cold air can gain access anywhere, so as to make a draft dangerous to the health. Furthermore, if close-fitting lids are provided, and kept closed when not in use, no unpleasant or unhealthful odors can escape; and as it is all a dark cellar below, even a child would meet with no repulsive sight if the little one should happen to look into the dark depths. From motives of economy and durability I would by all means have the foundation of brick or stone; then bank it up and plant grapevines or other choice fruit around it. A Niagara grapevine is growing near the one belonging to our home.

After we get to the end of our underground reservoir we shall have one pit containing no earth, and there is none to put into it. But the dirt from the first pit lies where it was thrown out. This may be carted so as to fill up the last one, or you can spread it over the surface and fill the last with dirt taken from the surrounding soil. We meet the same thing in ordinary trenching for market gardening. Of course, where we put in as much manure as I have mentioned, the heap of dirt at A will be raised up much above the general level of the ground. I propose to let this lie until the frosts of winter work it up fine for use, and this morning, Jan. 12, the thermometer is 6 degrees below zero, so you see I am going to make this severe weather serve me. Our potatoes and apples are safe from the effects of the frost, in that new outdoor cellar I have mentioned a few pages back. Our poultry and bees and other stock have comfortable accommodations; we have a large factory at least tolerably warm by steam-pipes this brisk morning, so we can go on with our work in spite of the frost.

Of course, I do not know what we shall be able to raise over those reservoirs, and on the ground between them. We have placed them from 20 to 30 feet apart. We shall, as soon as spring opens, test them with strawberries, raspberries, celery, cabbages, etc., and we think it quite likely we shall be able to get splendid crops on a soil heavily manured for *two feet* or more in depth, with a reservoir of water underneath it all.

CHAPTER VIII.

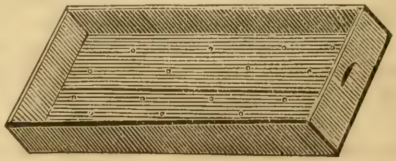
Whatsoever thy hand findeth to do, do it with thy might.—ECC. 9:10.

Now, friends, if you will pardon the digression which the advent of friend Cole's book has made necessary in our new book, we shall go on with "What to Do, and How to Be Happy while Doing It." The digression will, however, I hope, furnish many of you something to do; and if you are as happy while doing it as I have been during the past three or four weeks, I think the chapters which it occupies are right in place in our book. A good deal that I tell you how to do here I suppose will be done when you would not otherwise do much of any thing else. In fact, this book is written particularly for people who have spare hours, and times when they have not much to do.

Some of the things I describe cost considerable money, I know; but I do not intend to recommend things that will not ultimately save money in the end, or save health, which is more than money. It is now toward the middle of January, and the weather is such that many of you doubtless think ordinarily there is not much to be done outdoors. However, we should try to improve all weather suitable for outdoor work; and when you can not work outdoors, let us work inside. As a general thing, I believe it pays to have one or more thermometers about your premises. By watching the thermometers you can tell how the weather is turning, and make your plans accordingly. A thermometer is also needed in the cellar, to tell when your fruit and vegetables are at the proper temperature. By opening the doors and windows you can keep many things about as safely as they are kept in the cold-storage rooms; that is, keep them just as near freezing as you can, and not have them freeze. Apples will frequently begin to rot badly during mild spells in the winter, where, by the simple use of a thermometer, and keeping the matter in mind so as to close the doors and windows, a cellar full of apples might have been kept entirely free from rot. Friend Terry takes advantage of this in keeping his seed potatoes so they will neither rot nor sprout. Suppose you decide by the thermometer that it is too cold, or the roads are too bad, or that there is nothing outdoors that can be done profitably; or may be it is after dark during these short winter days that you have unoccupied time on your hands—what shall we do? We will do this: Learn how to make seeds grow. Have you ever tried making things grow? Very likely you have. May be you are one of these people who can make every thing grow that you get your hands on. The chances are against it, however, because there are not many such people. You can learn how to do it, however, just as surely as you can learn the multiplication-table.

MAKING THINGS GROW.

If you haven't good seed, the first thing is to get some. If you have seeds of lettuce that have produced just such heads as you wanted in former years, use that. If you haven't, get a five-cent paper of one kind, or have different kinds, if you think proper. Last season I had *nineteen kinds of lettuce* growing in one bed, and the experiment was worth to me certainly all it cost. There is one advantage in commencing with seeds in the middle of January, because you can have them nicely tested indoors before it is time to work in the open air. May be you have only a window, or two or three windows, in which to raise plants. If you have a little greenhouse, cold frame, or hotbed, all the better; or if you have not these latter appliances, you can start the seeds before the window now, and get some sash and make preparations for them while they are getting larger. Whatever you do, economize your space and make use of every bit of sunshine. If you learn to use economy in managing a square yard of sunshine, you will be prepared to use economy when you get outdoors on an eighth of an acre, a whole acre, or many acres. It seems to me every farmer will be a better farmer for having at some time in his life had practice with a single square yard of earth, and tried to see how much he could make that yard produce. The first thing needed is boxes to hold your earth. I would have these boxes uniform, and all just alike, even if it does cost some time and trouble. Here is a picture of one of them.

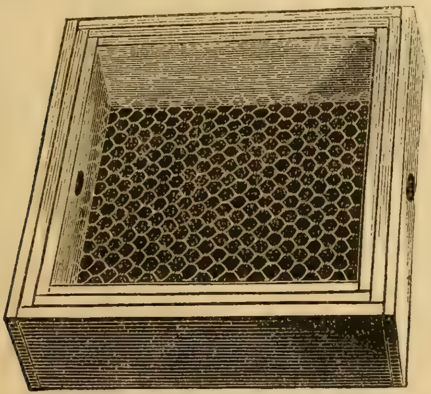


A BOX FOR RAISING PLANTS TO SET BEFORE THE WINDOW.

To have them light to handle I would have them made of ⅜ pine, except the ends, which are made ⅝. The bottom is made of two pieces—not necessarily, but they are better so, because then each piece can be nailed into the side-boards, making the box strong, even though the bottom is all thin stuff. For drainage, the two pieces that form the bottom should be, say, ¼ inch apart. Then I would have a dozen ⅜ holes bored as shown in the cut. The box is 3½ feet long, 15 inches wide, and 4½ inches deep, outside measurements. Should you make a little greenhouse or cold frame, these boxes will be just right to set on the benches; or if you have the benches filled with earth, 3½ feet is about as far as you can reach over while standing in the path. More of this anon.

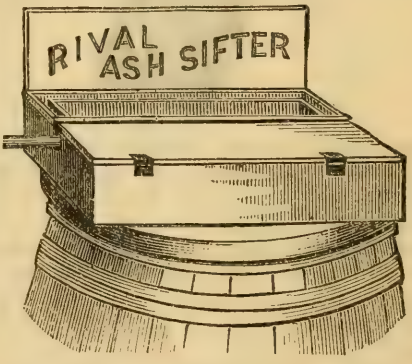
SOIL TO PUT IN THE BOXES.

Much depends upon this, and the basis of it should be good well-rotted stable manure. I would rather have this than bone dust, guano, phosphate, or any other fertilizer. The best thing to mix with the stable manure I know of is rotted sods, but you can not always get these handy. Perhaps the best you can do will be to get some soil from the richest part of your garden. If your manure and garden soil are both frozen up it will give you an appetite to dig out enough to fill a box or two so as to get things started. You can thaw them out near the fire, or perhaps in the cellar. If you can get hold of some peat from a peat-swamp, you want some of that also. A heap of it in the cellar will be nice to have. You will remember how much Mr. Terry and other prominent agricultural writers have said in favor of fine tilth. If they can afford to plow and harrow *acres* so as to get it worked up fine, *we* can afford to take some pains with a little box full. The nicest way to get soil for plants in a fine state of subdivision, and at the same time get out all the sticks, stones, trash, etc., is to sift it. By all means, *freeze* it thoroughly, and then thaw it before you undertake to sift it. If you have not a good sieve suitable for the purpose, you can purchase one for about ten cents. We give a picture of three such sieves in the figure below.



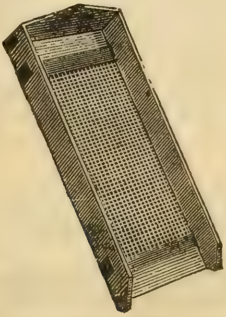
SQUARE SIEVES FOR GARDENERS' USE.

Sift the stable manure if you can. If you can't, break it up into little bits. If it is old enough and rotted enough, so you can break it up and make it go through the sieve, it is just what you want; but if it is the kind that is black, and can be cut up, something like cheese (beg pardon for the illustration), it will do very well, for it will soon work up fine by use. While speaking of the sieves, I wish to say that such sieves are very handy for many purposes in the household. The ashes from your stove, if you burn wood, make an excellent fertilizer, and are to be saved very carefully. Before using them they should be sifted, and every thing that does not go through the sieve should go back into the fire. Coal ashes are sometimes treated in the same way, and the coal and coke you get out of the ashes to burn over again will well repay you for the time and trouble. Some wood ashes will be tiptop to put in your seed-bed, but you do not want more than a teacupful in a whole box of earth, and it must be very thoroughly mixed with soil by stirring it up and sifting it in. Your muck, or peat, also wants sifting; and where you have much sifting to do, soil, peat, ashes, etc., a regular ash-sifter to put over a barrel is a nice and cleanly arrangement. We give a picture of the ash-sifter below.



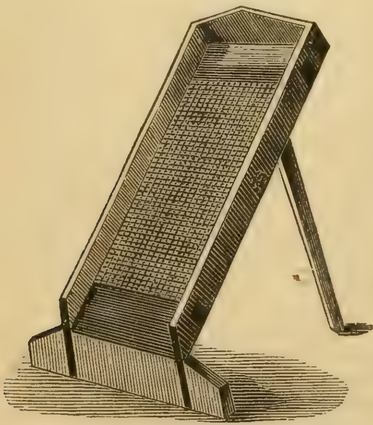
You will notice that this sifter sifts your material nicely in a barrel. The lids shut down so that the ashes do not fly around the room and make your wife trouble. Such a machine costs about $1.25. If your soil is a clay soil, a mixture of sand is excellent for raising most vegetables. Radishes, for instance, grow nicer in sand or gravel, properly enriched, than almost any thing else. While speaking of sand I want to say that a sand-sieve is a splendid thing for sifting soil, peat, etc., especially where you have enough to do to take it outdoors. We use one such as is shown in the cut on next page.

They are also nice for sifting gravel for making gravel walks; also for sifting coal. One end is to be propped up at such an angle that, when you shovel the dirt, sand, or gravel, against the upper end, it slides down of itself. An economical way to use such a machine is to have two wheelbarrows side by side. Stand the screen so it rests in one wheelbarrow, sloping over the other. Pitch your mellow soil against the top end; the fine dirt goes through into the wheelbarrow below, while the coarse particles run down into the other wheelbarrow; then wheel the contents of each where you want it. Such a screen, or sieve, made of galvanized iron wire, so it can not rust, costs $5.00. It is 2 feet wide by 5½ feet long. They are used by masons, coal-dealers, and for many other purposes. If you live near a large city, you can often get the sweepings from the pavements, which Peter Henderson considers worth as much as barnyard manure. Run it through the sieve as above, and it is ready for business. Below is a cut of this last sifter.



SCREEN FOR COAL, SAND, ASHES, OR GARDEN SOIL.

Where you are going over a still larger extent of ground, and wish to get out sticks, stones, hard lumps, etc., but don't care about being so very particular, a still coarser screen is sometimes handy—such a one as dealers in coal use largely. A very handy one is shown below, with a foot-board and leg.



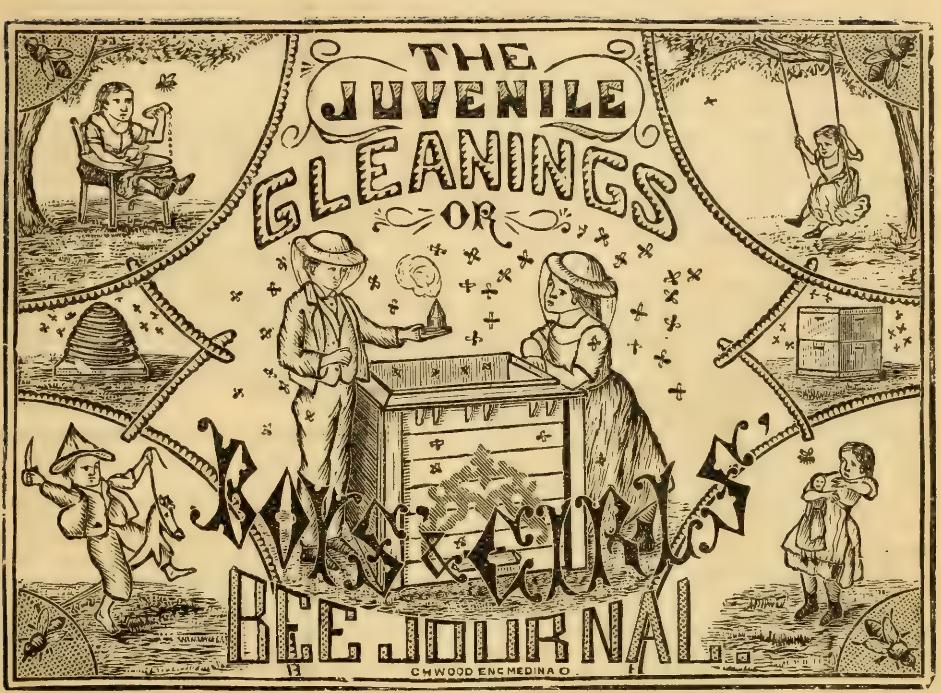
COAL-SCREEN, TO BE USED FOR GARDENING PURPOSES.

This last machine is the one we shall use for preparing the soil over our covered reservoirs, described in Chapter VII. We pass the surface soil through this to make it fine, and to get out all the stones and other impediments to high culture. This *debris* which is screened out is used for filling the overflow filters, which permit the water to flow from one reservoir to the other.

Now as we have discussed soils and sieves, let us sow our seeds. As no plan has given us such success as the one described by Peter Henderson, in his book entitled Garden and Farm Topics, we give it in his own words here:

> Since 1886 we have made many important improvements in culture under glass, particularly in the methods in use in starting plants of cabbage, cauliflower, and lettuce. The old plan of sowing the seeds for these plants in the open air in Sept., and pricking them off in Oct., and keeping them in cold frames, is gradually giving way to sowing in green houses or hotbeds in February, and pricking out in March, which gives a far healthier and nearly as strong a plant, by the first week in April, as those that have been wintered over. The past season we raised nearly half a million of plants in this manner, which we sold at $5.00 per thousand, a price as profitable to us as the plants were satisfactory to the buyers. We sowed the seed the first week in February, in one of our greenhouse benches, so thick that they stood twenty plants to the square inch. These we began to thin out, to prick in hotbeds, just as the first rough leaf appeared, placing a thousand plants in a 3×6 sash.
>
> The handling of that quantity was a big job, but I doubt if one plant in a thousand failed, owing, I think, to a plan we used in preparing the bed on the greenhouse bench for the seeds; a plan that I think well worthy of imitation in preparing a bed for seeds, that have to be transplanted, of any kind, whether outside or under glass. We used only two inches in depth of "soil" for our seed-bed, which was made up as follows: For the first layer, about an inch, we used a good friable loam, run through a half-inch sieve. This was patted down with a spade, and made perfectly level and moderately firm. On this was spread about one-fourth of an inch of sphagnum (moss from the swamps), which had been dried and run through a sieve nearly as fine as mosquito wire, so that it was of the condition of fine sawdust. On top of the moss the ordinary soil was again strewn, to a depth of about three-fourths of an inch. This being leveled, the seed were sown very thickly, and then pressed into the soil with a smooth board. On this the fine moss was again sifted, thick enough to cover the seed only. The bed was then freely watered with a fine rose, and in a week every seed that had life in it was a plant.
>
> Now, this seems a long story to tell about what most consider a very simple operation, but it is necessary to give these details for a thorough understanding of the advantages of the method. When the seeds of most plants germinate, where they are thickly sown, the stem strikes down into the soil, the roots forming a tap-root with few fibers, unless arrested by something. Here comes the value of our one-fourth of an inch of sifted moss, placed three-quarters of an inch from the top. As soon as the rootlets touch the moss they ramify, in all directions, so that when a bunch of seedlings is lifted up and pulled apart, there is a mass of rootlets, to which the moss, less or more, adheres, attached to each. To the practical gardener, the advantage of this is obvious: the tiny seedling has at the start a mass of rootlets ready to work, which strike into the soil at once.
>
> The advantage of the moss covering of the seed is not so apparent, in the matter of a free germinating seed, such as cabbage, as in many others; but in many families of plants it is of the greatest value. For example, last November I took two lots of 10,000 seeds of *Centaurea candida* (one of the dusty-miller plants so much used for ribbon lines); both were sown on the same day, and exactly in the same manner, in boxes two inches deep filled with soil; but the one lot was covered with the sifted moss, and the other with fine soil. From the moss-covered lot I got over 9000 fine plants, while from that covered by soil only about 3000. The same results were shown in a large lot of seeds of the now famous climbing plant *Ampelopsis Veitchii*, and in the finer varieties of clematis. The dust from cocoa-nut fiber will answer the purpose even better than sifted moss, when it can be obtained. The reason is plain: the thin layer of sifted moss never bakes or hardens, holding just the right degree of moisture, and has less tendency to generate damp or fungus than any substance that I know of.

To be continued Feb. 15, 1886.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

Thou shalt not covet . . . . any thing that is thy neighbor's.—Ex. 20:17.

THIS subject of our neighbors has been brought prominently to my mind this morning by contemplating the Bohemian-oat swindle. In order to bring the subject before the friends, I quote the following from the *Farm and Fireside* of Jan. 1, 1886:

> Originating in northeastern Ohio, the Bohemian-oats scheme has spread like a poisonous fungus throughout this and most of the neighboring States, until it promises to permeate the length and breadth of the land. Certainly it would seem that no man of average intelligence could fail to see at a glance that somebody must eventually be a heavy loser by this scheme, even were those primarily engaged in it to fulfill their contracts; yet we have been astounded to hear mentioned in connection with it the names of men who had previously stood above reproach. This scheme has frequently been denounced as a swindle by the local press where it has appeared, but these denunciations have not prevented its reappearance in some distant quarter. Moreover, it has been quite difficult to get at the real plan upon which the scheme was being worked, and consequently the sharpers operating it, by the aid of a few stool-pigeons employed in each new neighborhood, have been able to work it over and over again. In this and the preceding issues of *Farm and Fireside* we have presented the most complete expose of this business we have yet seen. The reader who follows this expose carefully will see that the scheme is most cunningly devised to feed upon the greed of unprincipled tricksters on the one hand, and the credulity of ignorance on the other; and that unless checked it will bring upon the farmers of the country an enormous load of distress.

Even the little boys and girls, I think, can understand this matter if I try to make it plain, and perhaps many of them have heard the matter talked over in their families already. When the agricultural papers came out and announced that these oats could be bought for 75 cents or $1.00 a bushel, while this association was calling them worth $5.00, and in some cases $10.00 a bushel, it would seem that any child should understand that there was something wrong; but men who have before been considered good men, and some of them, perhaps, professors of religion, have still pushed ahead, made crazy and greedy by speculation. Some of them have even gone so far as to say, "I don't care if the oats *are* worth only 75 cts. or $1.00 a bushel; so long as these men give me my $5.00 a bushel, what does it matter?"

When anybody goes to reasoning in that way, you may be sure he is in a bad state of mind. We all of us get into bad states of mind occasionally—that is, the most of us do. Just yesterday morning Huber was cross and peevish. I reasoned with him a little, but the "cross" would not go away. He saw the force of my reasoning, and he knew he ought to be a good boy; but he told the truth, even if he was bad. In reply to my question, he said, "No! bad boy." I presume he reasoned as I often have, in regard to this element of evil that sometimes gets such firm hold of us. He did not say so, but I thought by his looks he was thinking something this way: "Papa, I know I am a bad boy; but I am trying to be good, and the good won't come. I do not know what it is that makes me bad." Pretty soon he came to the point where he might have honestly said, "I am sorry I am bad." Just one step more, and he could think, "I want to be good." When he got to that point he was out of the filthy mire. A smile began to show itself dimly around the corners of his mouth, and finally out it came, and we had a bright good boy at the breakfast-table once more. Now, then, children, for the application: When these men get crazy for money gotten without any fair equivalent, they say, "I do not care if the oats *can* be bought for a dollar a bushel; if I can get five dollars for mine, and have a sure thing of it, I am not going to bother myself any further about it."

I will tell you, my little friends, how they get the five dollars for what is worth only one dollar. A whole neighborhood gets crazy over this new speculation, or new species of gambling, if you choose. A smooth-tongued agent manages, by hook or crook, to get a few good men among them, usually by telling them that it will not cost them any thing, and arranging it so they can't possibly lose; then after awhile he slips out of it and lets the responsibility of it rest on the members of the association. Men of capital, and usually those who are posted in all the tricks of the business, slip out through loop-holes previously arranged expressly for them. Men who are comparatively poor, who have mortgages on their small farms, perhaps, and who are, may be, not quite as well posted as their neighbors, in the end have to shoulder the responsibility; in other words, they have to make up the difference between one dollar a bushel and five dollars a bushel, so the scheme is one to rob poor men, and to put the proceeds into the pockets of the richer ones. What shall we do to avoid such traps and tricks? Why, keep entirely out of them, and keep out of temptation's way; don't even *talk* with these kid-gloved, smooth-tongued speculators. Shun even the appearance of evil. If your heart is full of love for God and love for your fellow-men, especially your neighbors, there will surely be no danger of your getting into any such scheme. Remember the commandment, "Thou shalt not covet . . . . any thing that is thy neighbor's."

In connection with this subject I wish the friends, young and old, would turn to the first chapter of Proverbs, and read from the 10th to the 20th verse. It would almost seem as if Solomon had the Bohemian-oat business in mind when he wrote these verses. If you know any Christians who have any thing to do with this awful piece of villainy, just ask them to read these verses.

Now, lest you think I am too severe from what I have said, I want to make two other extracts from the *Farm and Fireside*, furnished by Mr. Henry Talcott, a member of the State Board of Agriculture, and a banker, and a prominent citizen of Ashtabula County, this State. He replies to the editors as follows:

You have got hold of the elephant, exactly. We had one Henry L. Bacon to come here four years ago as the head-center of this business. I wrote up the business for our papers instantly, and tried my best to prevent our farmers from being swindled. I told Bacon, when he brought his first notes to my bank to try to get them cashed, that he ought to be put in the penitentiary at once, and, thank God, he is there now for seven years—sent from the Summit County courts in Akron. He made a big run of the business first, however. Our farmers were a set of fools over the business, and now lots of lawsuits are on hand in our courts as the result of it, and many good people are in trouble. I hope you will push this light before the farmers as fast as you can. HENRY TALCOTT.

And this:

As a rule, the Bohemian oats will not yield over two-thirds as many pounds of grain per acre as the Norway, Russian, or Welcome oats. I know this, and do not guess at it, because I have given all these kinds a most systematic and thorough trial. The Bohemian-oat swindle has been here four years, and I have seen and know the bottom facts.

A number of lawsuits, grown out of this business, are now on our court dockets, and so far the swindlers get beaten every time under the equity provision of the common law. No man can collect pay for a Bohemian-oat note, because the giver does not get value received, and the only way they attempt to do it here is to sell the notes, before due, to a third party, who can set up the claim of innocent purchasers. Fifty cents per bushel is all our courts have yet allowed as the value of the oats.

Ashtabula, O. HENRY TALCOTT.

LETTER FROM MRS. HARRISON.

SOMETHING ABOUT THE DETROIT CONVENTION.

CHILDREN:—I didn't see any of you at the convention at Detroit. Would you like to know who was there? I know you would, because I'm a child myself, only a little bit old. First and foremost was father Langstroth, cane in hand, his face beaming with happiness and good will to all. He said he had not made any money out of his invention; but whenever he met a bee-keeper he was warmly grasped by the hand, which was worth more to him than money. He told a friend, that whenever he needed any thing he told the *Father* about it, and he sent it. Father Langstroth used to preach; but he got sick, and could not do it any more, and he told his wife, "If I could only invent a hive, so that every poor family could have honey all the time, I should be happy," and so he is happy; and not only happy, but beloved, and first in the affections of bee-keepers. Strong men shed tears as they watched him leave the room to take the cars for his home at Oxford, Ohio.

Mr. Root, the president of the convention, married a daughter of Mr. Quinby. Now, I always feel as though Mr. Langstroth were the father, and Mr. Quinby the father-in-law of bee culture. If I tell you a secret about Mr. Root you won't tell, will you? He gets lots and lots of honey from his bees, and won't tell how he does it. Never mind; we'll find out ourselves, and we'll feel so good over it. When I went to school I never liked to have any one do a hard example for me; for if I did it alone I could snap my fingers and cry out, "I've got it! hurrah!" You have all heard of Mr. Jones, of Canada, haven't you? He went to Italy, Cyprus, and Palestine, after bees, and raised queens on islands a long way from shore. He is a good talker, and, Englishman like, he brags a dood deal; but nobody cared until he had the impudence to start a bee-journal in the queen's domain, just as if the United States could not furnish enough for all North America and the rest of the world besides.

The second day of the convention was Mr. Root's birthday (Uncle Amos). You all like presents on your birthday, don't you? Mr. Root got one—a nice book. He was surprised. Some thought, that because a woman was on the committee she would tell; but she didn't, and so he hadn't any speech ready, and could only say, "God bless you, my friends; God bless you."

Professor Cook was feeling first rate—was in the best of humor. He looks as if he lived on apples, pears, peaches, strawberries and cream, with oatmeal and graham bread, and never tasted of pon-horse, pigs' feet, sausage, head-cheese, and mince pies. I tell you, it makes a pile of difference what a man is made of.

I could talk to you by the hour of what I saw at the convention, but I am afraid of the editor's gavel, "Out of order!" **Mrs. L. Harrison.**

Peoria, Ill.

Now, my good friend Mrs. H., I am going to add to the list of people who were there. In the first place, you were there yourself, and it always does me good to see your genial face when I get to any of the bee-conventions. Miss Lettie Wilkins was also there, and quite a goodly number of ladies whose names I have forgotten. And now you have told about what *we* did, I am going to tell the children that, when I had to leave to take the train, you said you wanted to throw your old shoes after me for good luck, and I remembered it too. You say that President Root wouldn't tell how he got such lots and lots of honey. Perhaps the reason why is because he has already told it in his excellent book, Quinby's New Bee-Keeping, and he does not want to be telling it over and over.

GOOD REPORT FROM A JUVENILE.

ALSO A KIND WORD FOR OUR FRIEND OLIVER FOSTER.

I WILL send our report for 1885. My brother Herbert started in the spring with a stand of hybrids. He bought a nucleus (one pound of bees), with tested queen, of Oliver Foster (and he is a square man to deal with). We got it May 21. In all my brother obtained 205 lbs. of comb honey, of which 70 lbs. came from the nucleus, besides moving the nucleus when they were strong in bees, and letting the field-bees go to make another swarm. He sold all his honey at from 15 to 17½ cts. per lb., giving him $31.50 for his honey. Herbert has now 3 stands, strong in bees and honey. The rest of us had 3 stands in the spring, and increased to 8. We bought two more nuclei of friend Foster, after July 15. They did well, and mine made 20 lbs. of surplus in sections, besides being full below. All together we sold 535 lbs. of comb honey, selling the most of it for 15 cts. per lb. We have 13 hives in all. They are packed for winter on their summer stands, with plenty of honey in the hives, and about 200 lbs. in frames, to feed in the spring. We have the A B C book, and could not get along without Gleanings. We keep our bees mostly in the Kretchmer Simplicity hive. **Florence Green.**

Emerson, Iowa, Jan. 5, 1886.

Friend Florence, your report is a real good one. And so a nucleus, bought after July 15, gave you 20 lbs. of comb honey, did it? Now, this 20 lbs. of comb honey probably paid the cost of the nucleus, and you have the bees and stores left. If we could all do as well as that, bee culture would be fun, wouldn't it? We are glad, also, to know that friend Foster succeeds so well in pleasing all his customers.

CHARLIE'S EXPERIENCE WITH BEES.

WHY DO BEES RUSH TO THE FIELDS WHEN FED IN THE HIVE?

MR. ROOT:—This winter has been a mild one so far. The thermometer has ranged between 30° and 40° nearly every day, and many nights it has not got down to freezing. The bees have had several flights during December, and they also flew on New Year's day. The way we prepared our bees for winter was to fill the upper story of the hive with soft dry oat chaff thrown in loosely. Most of our swarms gathered enough honey to winter on, but some of them had to be fed in the fall. To avoid robbers we fed at night. If we fed them before it was really dark, sometimes one of the swarms that we fed would rush out in great clouds, roar about through the air, come into the house, and some of them in their excitement would go out to the buckwheat flowers, although it would be nearly dark. They were very cross at these times. They would return at dark, and in the morning would be as peaceful and quiet as if nothing of the kind had happened. While doing this, not a bee would be moving about the other hives, so it could not be robbing. I think that a bee may have stolen a load from the vessel containing syrup when it was sometimes set out to cool, for often I saw a robber at the syrup. When he emptied his load and again started forth, part of the swarm followed him. Do you think this was the cause of it? From this we took warning not to put syrup within the robbers' reach any more. We also fed some in December when the days were warm enough for the bees to fly.

MOVING A WEAK COLONY THAT HAS BEEN ROBBING, A COUPLE OF MILES AWAY.

Last spring we had a box hive that got so weak that only a small handful of bees remained, and they could scarcely be seen at all, away back among the combs. The robbers bothered it so that we at last moved it a couple of miles away. This was during locust bloom, and before basswood blossomed it had built up to a heavy swarm. We had another swarm a little larger than this one that built up and cast two swarms.

THE ADVANCE GUARD THAT PRECEDES THE SWARM; PUTTING A LARGE SWARM INTO A SMALL HIVE.

In swarming time last summer a runaway swarm came past me, in which I noticed that a little band of bees were going along in advance, followed by the main body. In 1884 we put a large swarm into a hive that was too small for it. It absconded; and while attempting to get them into another hive the queen must have accidentally got killed, for the swarm attempted to return to the hive that they absconded from, and were nearly all killed, because they got into another hive near by containing bees. They rushed through the hive and into the air with sad, wailing sounds, clearly indicating trouble and distress, and that trouble was undoubtedly the loss of their queen.

A CAUTION IN REGARD TO JARRING HIVES UNNECESSARILY.

Will bees consume honey wastefully when jarred? In the fall, one of our swarms was jarred so that it tore open some of its honey, and filled themselves with it, and every time for some time after that, that I looked into them (although I would not jar them at all), they would seem excited, and would dive into the cells. When disturbed some of the bees make quick, sharp sounds which I can hear by pressing my ear to the side of the hive. On warm days this is kept up all day, and on cold ones for a few minutes only. They also make this sound while at work on a feeder. Will the slight jarring that *will* sometimes be made cause them to wastefully eat honey? and are they any more liable to do so in winter than in summer? Are hybrids any more apt to do it than Italians?

CHARLIE L. GREENFIELD, age 14.
Somerville, Ohio, Jan. 2, 1886.

Friend Charlie, you have given us some most valuable facts. You have also called attention to the other strange phenomenon connected with bees. We have placed to your credit on our ledger one dollar, and we hope you will be able to give us more such items from actual experience. Your letter plainly indicates that you have been among the bees, and that you are a thinking boy. In regard to the bees starting out for the buckwheat when you fed them, I have noticed the same thing. They had doubtless been at work on the buckwheat in the fore part of the day; and as they had scoured the country in the afternoon, they knew pretty well that the buckwheat was the only source of honey; so when their comrades came in laden from the feeders, they concluded, according to the best bee-sense they possessed, that the buckwheat must have taken a sudden freak of yielding honey at dusk instead of dawn, so off they put for the buckwheat field. You see, they jumped at conclusions just as boys and girls do sometimes. In the A B C book I have mentioned feeding a colony one evening that had been getting honey during the day time out of the honey-house, because somebody had left the door open. Well, as soon as a few bees got loaded up from my feeder, and walked leisurely into the hive, a regular stampede occurred. The bees just poured out of that hive, flew in my face, and buzzed past me and put for that honey-house door. They thought somebody had left the door open again; at least they could not think of any other place from which their comrades had obtained such loads in so short a time. Now, there is a valuable point indicated here. Bees understand each other a great deal as we do, only they do not have a language as we do. Had their comrades been able to tell them, "Hurrah, boys! the boss has just put a saucerful of feed right on the alighting-board for us," the bees in the hive would have tumbled pell-mell to see who would get to the saucer first. But you see they did not tell them any thing. They only came in with great loads, and made haste to dump it into the cells. Perhaps they buzzed their wings and wiggled their bodies as they do when the honey first comes from the dandelions and apple-bloom.—A great many times the best thing to do with a hive that has been almost used up by robbers is to carry it a couple of miles away.

What you saw in front of that swarm was what the bee-books have termed the "advance guard" that leads the swarm to the particular tree selected by this same scouting party.—Bees will consume honey wastefully, I think, when they are stirred up during a dearth of honey, or when the weather is too cold. They are more liable to do it in winter; and cross hybrids, or cross bees of any race, are more liable to do it than pure Italians or gentle bees.

HOW OLIVER FOSTER PUTS UP AND SHIPS HIS BEES.

THE CALITHUMPIAN BEES.

BACK a few numbers of GLEANINGS you said that you would like to have a report of the way in which Mr. Oliver Foster puts up his bees to make such successful shipments. Pa got 1¼ lbs. of bees, a comb of brood, and a tested queen from Mr. Foster last May. They were in a light case 4 inches wide, and deep and long enough to hold a Simplicity frame, a wire nail driven down through the ends of the frame and into the case, the nail sticking up just far enough to get the claws of the hammer under to pull it out easily; then a piece of old tough brood comb was wedged between the comb and case to hold all steady; a wire cloth was tacked over the top, two screws in each side of case, and wire fastened to them, and passing over the top for a handle.

They came through (800 miles) in splendid condition. They were three days and four nights in the case. We took them out of the case and got them in the hive in short order, and in a few minutes they were carrying in pollen from fruit-bloom for all they were worth. Pa said they just took the oath of allegiance, and went right to work like good and loyal subjects of "Her Majesty."

I have something funny to tell you about No. 16, the hive with the Foster queen. Bennie A——, a boy 14 years old, who had never seen Italians, was standing in front of the hive watching the bees, when he asked, "Are these Calithumpian bees?" You see he could not think of "Italians," so he did the best he could. Such a laugh as we all had, and pa laughed until he almost cried. Of course, you know what we call Calithumpian. Those fellows who parade in the processions on the 24th of May and other holidays, dressed in ridiculous costumes and masks. We have dubbed that hive the Calithumpian, ever since. It is too bad, too, to give them such afunny name, for they have done wellhis summer, and pa says that is one of the best queens he has. Our bees are nearly all in sawdust hives, with sawdust cushions in the section-case on top.

I have a brother, Roy, 8 years old, and a sister, Ruby, 5 years. We are all interested in the bees. Isn't it a funny little fellow, who knows every thing just as soon as he is born, as a bee does?

Now, Mr. Root, I have tried to write this just as the printers want it, on one side of the paper, and all that. You see my pa writes for the county paper. If you think it would do for GLEANINGS, I will write and tell how we made an aquarium, with a pretty fountain in the middle, for our dining-room.

SPERRY DUNN.
Ridgeway, Ont., Can.

Very good, Sperry; but we wanted to know how Mr. Foster puts up bees without any brood or combs. The package you got was a one-frame nucleus, which is all right, but it takes a comb of brood and honey out of the hives every time he sells a pound of bees.

JUVENILE·DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

IS it not a little strange why young birds should leave their cosy nests? why bees swarm, and why grown-up young folks should abscond and leave the old house with its fond recollections? Yet it is not so *very* strange after all; at any rate that *first* swarm from the "Root Bee-Hive" thinks so! Yes, they have recently been visiting New York — the great metropolis where the busy hum of busy life prevails. As the parent stock has said, it seems a wonder that some one does not get run over. Amid such a hum-drum, rattle and roar, ears are no surety against impending danger, and when crossing the street you have to look several ways at once, if that be possible, or you may get knocked down by a cart-wheel or a horse tugging at a street-car. The streets of Cleveland, Detroit, and Chicago, where there are no elevated railways, bear little comparison to those of New York, in the amount of noise and seeming confusion.

We visited many different places which you may have read of, or, possibly, have seen, such as the Brooklyn Bridge, from whose height we see in the distance Hell Gate, of which we have read so much of late; Central Park, a wonder in itself, occupying a vast domain of rocky land in the heart of the city; a Japanese village, modeled after those seen in the native country, and where all the various arts are represented; the Eden Musee and many other places, to say nothing of the various streets which are celebrated in themselves.

As these things are all quite familiar, or have been fully described in some of our best magazines, suppose, little folks, we take a boat-ride in N. Y. Bay, our point of destination being Staten Island. As we start we can begin to form an idea of the size of the Bridge as seen on our left. Yonder is Govenor's Island, upon which is situated an old fort. Further on to the right as we glide along, is the pedestal upon which is to be placed the Goddess of Liberty, of which we have read so much. All along our course are tugs, yachts, and sail vessels. Here is a steamer just coming in from the ocean; there is one just going out to sea. Thus the water in the bay is a fair sample of the life seen upon the streets. Pursuing our course a little further we finally arrive at Staten Island. From this the old Commodore Vanderbilt formerly ran his ferries. On landing, after a long walk we arrived at Fort Wadsworth, at the upper end of the island, and just opposite the Narrows. From this point we see dimly the ocean, and across the Narrows two other forts—the names of which we do not know. As we look at these vast masses of earthworks like mountains, and the solid walls of masonry, with huge guns mounted here and there, as if about to sweep every thing on the water, we feel like exclaiming, "Woe unto you foreign nations that dare to invade this harbor." A little inquiry, however, reveals the fact, that these guns are of but little service now, being relics of past wars. The ironclads of to-day would pass these forts unharmed. Nothing short of a torpedo, or a cable stretched across the Narrows, could prevent them going down. Neither would the stone walls offer any resistance to the heavy breech-loading rifled cannon. Wise men are asking the question why Uncle Sam does not build a navy and refit these forts, thus rendering ourselves more secure from invasion. I suspect Uncle Sam thinks there are other things of vastly more importance. Our resources are almost endless, and if any one can put himself in fighting trim on short notice, it's Uncle Sam. More than all, "It is not by might nor by power, but by my Spirit," saith the Lord.

Well, well! my little (?) letter is already too long and I'll have to stop short right here. Perhaps you inquire whether the "better half" was along. I reply, that said "half" *was* on hand, and really tired *me* out walking.

ERNEST.

BEES, HICKORYNUTS, ETC.

We are wintering three stands of bees. We have two packed in sawdust, and one in the cellar. We extracted 100 lbs. of honey last season. Last year was a good year for bees here, but there was no sale for honey. Last fall was a good year for hickorynuts. My brother and I gathered about three bushels.

ALBERT MCCURDY.

Trafalgar, Can., Dec. 27, 1885.

FIVE CENTS FOR SEEING THE FIRST SWARM.

My pa has some bees, and so has my grandpa. Last summer we little ones had to watch them at swarming time; the one who saw the first swarm come out got five cents. I go to day-school, and to Sunday-school. I had a nice piece to speak the evening before Christmas.

FREDDIE A. LAROSH, age 8.

Pekin, Ill., Dec. 27, 1885.

FROM 6 TO 12, AND 465 LBS. OF HONEY.

Pa took the first premium on Italians and black bees, and extracted honey, and second on rabbits, at our county fair. We made a fish-pond this fall, and have now made applications to the U. S. Fish

Commissioner for carp. Pa wants to know if the fish that he gets this winter will spawn next summer. We took 465 lbs. of honey last summer from 6 colonies, spring count, and increased to 12 and sold three. **JAMES SHENEMAN.**

Pharisburg, Ohio.

No, James, the fish the Commissioner sent you this fall will not spawn next season unless they send out larger ones than any I have seen coming from the various State hatcheries.

ANOTHER BEE LIVED 19 HOURS AFTER STINGING.

I let a bee sting me at 1:30 o' clock P. M. Wednesday, and he died at 8:30 A. M. Thursday. He lived 19 hours. Our bees are wintering nicely. I have 4 of my own. I hived our bees last summer. My brother got 3000 lbs. of honey this year. He has 100 swarms. He ventilates the cellar by a stovepipe from the sitting-room stove, and an opening in the cellar wall, to let the air from outdoors come into the cellar. **HERBERT HUTCHINS**, age 13.

Massena, N. Y., Jan. 1, 1885.

STINGING LIZARDS.

I am a boy 14 years old, and I like bees. We have 14 hives. We had them Italianized last spring, and lost only 2 queens out of the 14. Isn't that pretty well for beginners? There are a good many bees around here. Bee-stings do not hurt me. We have sheep and I like them too. There are lots of "stinging lizards" here. The winter is very late here. Some of the trees have leaves on them yet. There are a great many wild flowers in this country, and "bucking ponies" too. **EUGENE FOWLER.**

Davilla, Texas, Dec. 8, 1885.

SAMMIE TELLS HOW THE BEES CLUSTERED UPON THE GROUND.

My papa keeps 23 hives. He commenced with one swarm. I will tell you what a time my papa had to save them. One bright sunny day last spring the bees came out to take a fly. They flew all around the yard, and when my ma went out in the evening to feed the chickens, she happened to see that the bees that were having such a nice fly were all lying on the ground. So my ma took a large crock and picked them all up and brought them by the stove, and they soon commenced to fly. It was then about five o'clock, and a little later the bees were all on the window. So my ma then sent to have papa come home and see to them. My papa brought the hive in the kitchen, thinking the bees would go in; but instead of that, those that were in the hive came out on the window with the rest, so pa moved the hive up to the window and made some syrup of sugar, and filled some comb and laid it near the entrance, and then lighted the lantern and set it next to the comb, and the next morning when we got up the bees had all gone back into the hive. **SAMMIE SEITZ.**

Clarence, N. Y., Dec. 7, 1885.

Sammy, my impression is, from your description, that those bees were out of stores, and they came out on the ground because they were starved. I suppose you fed them enough to prevent any such mishap occurring again.

TWO HIVES KNOCKED OVER BY A BLIND HORSE.

My pa takes GLEANINGS, and thinks it is a most excellent paper, and I am taking quite an interest in reading the children's letters. I have finally been seized with the idea that I should like to try and write you a letter myself, but I suppose there is nothing that I can tell you about bees which you do not know already, except it be some little incidents that have fallen under my observation. There is a small boy living here. His father and mother are dead, and he has no other home, so pa and ma have given him a home with us. His name is Roy. When he first came here he did not know much about bees. Pa told him he must keep away from them or they would sting; but he did not seem to believe that those little flies could hurt him very much. So one day when he thought no one was seeing him, he went up to a hive, stuck his bare toes right into the entrance, and you may be sure that it did not take the bees very long to convince him that he had better keep away. One day this fall pa let the horses into the orchard to feed down the grass among the trees. One horse being blind, he wandered down among the hives and got stung. He then started to run; but not being able to see where he was going, he ran "kersmash" against a hive of bees, and sent it tumbling two or three times over. He turned short about, and ran right against another hive, and upset that also. No great damage was done. Through all this excitement pa got but one sting, and that was by a bee which was tangled in the horse's mane, where he took hold to lead him away. Pa takes four bee-papers and a number of other papers. I take the *Youth's Companion*. **LILLIE BULL**, age 13.

Seymour, Wis., Dec. 31, 1885.

Thank you, little friend. I can imagine the scene that ensued. Your father certainly did well to have only sting; but, how about the old horse? The number of accidents we have had of this kind, ought to warn us to be careful about allowing horses a chance to gain access to the apiary. **ERNEST.**

Lillie, there is a *big* moral to your little story. Never let a blind horse loose where it is possible for him to get at bee-hives. First, because the poor horse is made to suffer, possibly; second, we have no right to make the poor bees suffer, as they do when their hives are turned over; and third, the owner of the horse and bees suffers from the loss of his property, more or less.

"ITALIANS A GREAT DEAL BETTER THAN BLACKS."

We went into winter quarters with 68 colonies, stores rather light. Our apiary is well Italianized from Hayhurst's best Italian queens. We like them a great deal better than the blacks, on account of their gentleness and being so easy to handle. We use the Langstroth hive, four inches short. Should such a hive be called Simplicity, or not? If not, then what should it be called? Bees are not so plentiful in this vicinity as they were a year ago. But very little honey was made during the latter part of the season; in fact, the season has been poor for section honey. Father traded two hives with bees for a sulky for my brother to carry the mail with next summer. Father hires it carried through the winter. **CHARLIE H. BLACK**, age 9.

Ellis Mound, Ill., Dec. 14, 1885.

Friend Charlie, the name "Simplicity" hive has been given to it principally because of the simple way in which it is made—a box without top or bottom, and so made that any number can be tiered up, excluding wind and rain. A hive thus made I should call "Simplicity," no matter what dimensions the frames are.

A LITTLE GIRL WHOSE GRANDMA HAS 52 COLONIES; CANARY BIRDS.

I am staying with my grandma this winter, and going to school. My grandma has lots of bees. She has 52 colonies, 42 in the cellar and 10 outdoors, packed in leaves. I helped to rake the leaves to pack them in. The bees did not make much honey last season. We have a pair of nice canary birds, and they are just beginning to sing. I feed them every morning before I go to school.

NELLIE G. MARTIN, age 11.

Grandview, Iowa, Jan. 7, 1886.

Sister Maude has a canary bird something over a year old. You just ought to see how saucy he can be. Why, he seems to have a particular spite at me. When he sees me coming he will begin to scold and bristle up for a fight. How he does delight in pecking at my finger! and he can hurt too. Sometimes we put before him a looking-glass. Do you think he admires himself? not a bit of it. He thinks it is another bird, and the little "goose" will fight at his imaginary foe for nearly half an hour sometimes.

ERNEST.

FROM 2 TO 10, AND 60 LBS. OF HONEY; TIERING DOWNWARD.

My papa had two box hives of bees in the spring, and he transferred them as the A B C book said, and had very good luck. He increased to ten hives; got about 60 lbs. of honey from them, and made two nuclei. They did very well and papa fed them. I like to see the bees take their feed. Papa has packed eight of them in sawdust, as James Heddon says, and one as Cyula Linswik says, and one is not packed at all. The one that he packed as Cyula Linswik said, came out of a hole there was in between the chamber floor and the wall below, and papa sawed out a piece of the floor where they were, took out the bees and honey, and gave the honey to a man. Papa fed them with sugar syrup, and they are in good shape now. He tried some in two other houses, and could not get them. They built the comb down between the walls, and carried off some of the feed down there. Papa got stung once, trying to get them out of the house.

My brother wrote about papa buying the bees at auction. There was a man who bought a hive of bees when papa did, and put them up high under an old shed. They did not swarm, but built comb on the under side of the hive. They have been there two years now. Papa went to see them last summer. They had as much comb under the hive as they did in it. The comb under the hive was covered with bees, and the man said the bees covered the comb the fall before that way, and they wintered so last winter, only they kept working up into the hive through the winter, but did not all get up until spring.

BELLE M. WANZER, age 9.

Litchfield, Ct., Dec. 10, 1885.

MOVING BEES IN A SPRINGLESS WAGON OVER A ROUGH ROAD.

Mr. Ernest R. Root:—As you have charge of the juvenile department I shall address you instead of your father. As I was named after you, I think you will be more apt to give room to my report, if report you call it. I *suppose* I was named *after* you. I am eleven years old, so you will know whether I was named *after* you or not. My papa is taking GLEANINGS; and of the dozen papers he is taking, I am quite sure he likes it best. Pa is much interested in bees. The Rev. Granville Houchins, who is going to assist pa this year in bee-keeping, says pa has the bee-fever. Mr. Houchins has had much experience in keeping bees. He is a preacher and a school-teacher. I am going to school to him now. Mr. Houchins has an A B C book that your father wrote. Pa has "Quinby's New Bee-Keeping."

Mr. Houchins and pa bought 19 stands of bees out on Flat-Top Mountains, about 25 miles from here, and the way is *very* rough. The bees were in hollow-log gums. Now, the way they got the bees home is what I wish to report. They hired a heavy two-horse wagon, *without springs*, as they could not get one strong enough *with* springs to bear the bees up over the rough roads. The wagon-bed was not large enough to hold all the gums, so they took out the hind gate and laid some long plank in the bottom of the bed; then they turned the gums bottom up and tacked some old cloth on the bottom of the gums. They filled up the wagon-bed with the gums, after they had put some straw in first; what gums were left they put on the ends of the planks that were put in the bottom of the bed, and which were longer than the bed. Then they put some plank on the sides, and fastened all in with rope. Mr. Houchins thought the bees would smother, so he got an old wire fly-trap and cut it up in small pieces; then he cut some pieces out of the old cloth he had nailed on the mouth of the gums, the same size of his wire pieces; then he sewed the wire pieces over the hole. This was to give the bees fresh air.

AN ORIGINAL SUBSTITUTE FOR WIRE CLOTH.

He did not have wire enough, so he got a lot of goose-quills and cut the ends off so as to leave them hollow; then he cut beards on the quills, on each end, commencing in the middle; then he put the quills through the cloth. The beards would not allow the quills to work out. The quills were to give the little fellows breath. The bees were three days and nights on the road, owing to the bad roads, rainy weather, and high water. They all came through all right except one hive, and it only had two or three dozen dead bees in it. This was because it was not quite so well ventilated as the others.

ERNEST B. HUGHES.

Pipestem, W. Va., Dec. 10, 1885.

Your father must be one of the old original subscribers of GLEANINGS to have named you after me. Let me see: GLEANINGS is 13 years old this month—just the age of Blue Eyes, and I at the time was 10 years old. I declare, it makes me feel old, and yet I hope I shall never be too old to be young.—Your father certainly did well to move 19 swarms 25 miles over a rough mountain road on a wagon without springs.—You have a very original substitute for wire cloth, but in what respect do the bearded goose-quills assist in the ventilation? I should think that small holes through the cloth would answer equally well. Perhaps I do not "catch on" to the idea.

ERNEST.

HAS LOST ONLY ONE SWARM IN SIX YEARS.

My pa has 55 swarms of bees. He has lost but one swarm of bees in six years. We got over a ton of comb honey this year. I help with the bees what I can. I have a little brother six years old. He and I go to school one mile. I also have a little baby-brother. He never saw Christmas till the one just past. He is three months old, and can laugh and play. **ALTON D. HARMON**, age 9.

Cambridgeboro, Crawford Co., Pa., Dec. 29, 1885.

SEALS.

When I was at Santa Barbara last I heard that there were some seals in cages on the wharf, so I went down to see them. There was an old mother and her little one in one cage, and three larger ones in another cage. They caught them from one of the islands twenty miles from Santa Barbara. They caught them with the lasso; and when they saw one they would all throw their lasso at him and catch him by different parts of the body and drag him on shore and put him in a cage that they had ready for him. They repeated this until they had caught those that I mentioned before. They then sent them to Santa Barbara for the people to see. The next morning they took them to San Francisco for Mr. Woodward, for his garden. They had very mild eyes, but for all that they were very fierce. They would snap at you if you put your hand near them. They are so very quick that they would turn clear over and grab a stick so quick that you could hardly jerk it away in time to keep them from grabbing it. Some of the boys were trying to pull out their whiskers, when the owner came along and made them stop. **ERNEST C. HILTON.**

Los Alamos, Cal., Dec. 26, 1885.

At Chicago, a couple of years ago, after I had visited T. G. Newman's place of business, I went to Lincoln Park. Among the notable features of this resort was a seal, or, perhaps, a sea-lion. At any rate, he would swim in the water at an astonishing speed, and bark very much like a dog at the passer-by. I remember that one old gentleman pointed his gold-headed cane at the animal's nose. At this the seal seemed immediately to take affront, and, with wonderful sagacity, swam to the other end of the pond. Here he disappeared under the water, and almost immediately reappeared directly in front of his offender, and then with one tremendous splash almost drenched the possessor of the cane. As you say, they seem to be wonderfully quick and keen. **ERNEST.**

THREE BEES DIE FROM THE EFFECTS OF THEIR STINGS IN EIGHT, SEVENTEEN, AND TWENTY HOURS RESPECTIVELY.

My brother keeps bees, and we let three sting a piece of soft buckskin, and they lost their stings. We put them in a cage and feed them all they wanted to eat. One lived eight hours, one seventeen, and the other twenty. I have Our Homes, part first and second. I read them out loud to mother and father, and my sisters and brothers. Mother says the books are worth one dollar. I have two brothers and two sisters; my brother likes Our Homes. **NETTIE H. CRANSTON.**

Woodstock, Ohio, Dec. 20, 1885.

Thanks for the additional light you furnish. In former cases bees have lived four, five, and six hours after having stung; but you give an incident of one surviving 20 hours. Now, while we think we have established with almost certainty that bees die after the operation, yet this may not be invariably the case. We have been led to suppose, or, rather, an opinion has prevailed, that bees have not only lived, but have even gathered honey, after losing their sting. I have seen this statement somewhere in one of the bee-books. Does any juvenile or anybody else know of such a case, or that a bee lived two days or after? In dealing with science we must deal exactly, and must not jump to the conclusion too soon, that bees *always* die soon after losing their sting. **ERNEST.**

REPORT FROM A CARP-POND; ALSO ABOUT THE CALADIUM ESCULENTUM.

Grandpa has 75 hives with bees, and pa has 4 stands. We live with grandpa. I have five brothers and two sisters. My ma is dead. I have a little blue-eyed sister nine months old. My ma died when she was just eight days old. Grandma has the baby to take care of. Grandma says she writes grandpa's letters to you. She says she sent you a Caladium-esculentum root. Did you ever get it? Grandpa has a fish-pond with lots of German carp in. Last summer we ate some fish. Grandpa says they are about as good as shad.

Pekin, Ill. **IDA B. LAROSH**, age 10.

Yes, friend Ida, we got the *Caladium esculentum*, and it grew nicely; but we did not see water dripping from the leaves, unless it was kept very wet. I presume if it grew in a swampy place where the ground is very rich it would have water on its leaves all the while. Give my thanks to your grandma, friend Ida.

A LIVING FLY-TRAP; HOW MANY FLIES WILL A TOAD EAT?

Your article in GLEANINGS last summer, about toads, was very interesting; and as we are now allowed to write about our pets, I will tell you about a pet toad we once had. A few years ago one came into our summer kitchen through a hole in the floor. We allowed it to stay and catch flies, so after that it would come up every day. One day we put some sugar on the floor to attract the flies, and when the toad came up we counted the flies it caught. It ate 150; and seeming to think that enough for one meal, it went away. I think a toad is a splendid fly-trap. Papa says: "If you go to your carp-pond next spring about the time the little 'pets' close their concert for the season, you will likely hear a musical note in a trilling monotone; and if you look closely you will see Mr. Toad, with head erect and chest expanded, pouring forth his song of love." He also says: "The little *black* polliwogs become toads, and the brown ones frogs." I will tell you about our bees in my next.

ETHEL J. BEATTY.

Shaw's Landing, Pa., Dec. 28, 1885.

Thank you, Ethel, for your very interesting letter about your little pet. You have a capital fly-trap indeed, and I should say that master Toad would not have much room left after having dined upon 150 flies. Whew! I wonder if he felt as little boys do after they have had their Christmas dinner. I fancy bees would go down the same wide mouth to destruction, could his toadship but have the chance. Most certainly we like to hear about pets when the spirit of the fine print at the head of this department is adhered to. This you certainly have done; and to encourage others I think we shall send you a chromo. **ERNEST.**

OUR HOMES.

Thou shalt love thy neighbor as thyself.—MATT. 19: 19.

FRIEND ROOT:—You are a Christian, and have had long experience, hence I ask your advice. I was once a professor of religion. I was young, and became a backslider. I have never since enjoyed myself. I saw more happiness while an active member of the church than I have ever seen in the long years since. Now, on the first day of January, 1886, I started again, and am going to join the church and try to be willing to bear my cross in every instance. I owe a good many debts, most of them small ones, and I am going to write or call on all my creditors and let them know that I am now going to make restitution for my sinfulness just as fast as the Lord will let me. My prospects are at present very flattering for the coming season. Have I the right, as a Christian, to invest in one or two bee-journals as long as I am owing debts? Now, it seems to me that it would be right for me to invest in about two good journals, as I believe by such an investment that I could then make enough more than I would if I took no journals. Am I right? If right, will you let me have GLEANINGS for 1886, and let me send you untested Italian queens, or money, whichever is most convenient, in June, 1886, subscription for 1886 full?

I want to be able, from this time onward, to do just what my conscience tells me is right—to pay every man just what I owe him, and always do a little more than I think right, rather than to do any *less* than my conscience tells me is right. I always thought I was a sort of moral man, but I can now see how useless my life has been, to what it might have been had it been spent in the service of my Master. I could write much more, but it seems to me wrong to occupy any more of your time. Pray for me that I may ever be a servant of God henceforth. X. Y. Z.

Although the above letter was not written for publication, I am sure our friend who writes it will excuse me for using it in this way when I assure him I think the story of his experience and trials may be a means of helping many another brother. I thank you, friend X. Y. Z, for the great confidence you repose in me in wishing for my advice, and most gladly do I give it, and most gladly do I pray for you that you may hold out and prove faithful; for if you do, I *know* that God will bring you safely through all your troubles.

In regard to the question you ask, and all other questions of this kind, there may be differences of opinion; and very likely many of the brothers and sisters will think I am a little extreme and a little severe in the plan I would recommend; but, dear friends, I have had years of experience in this matter in watching boys and girls who had foolishly let their expenses go beyond their income, as well as older people; in fact, this one sin of contracting debts that can not be paid has been one of the most grievous in leading astray those who seemed to have started well, but got off from the track. As I understand the matter, *I* am not the one to advise as to whether you should take a bee-journal or not, or make other investments of a like nature. So long as you are owing an honest debt, the money you have in your possession, as I see it, is not yours: it belongs to these friends who have been so kind as to credit you; and when any question comes up as to investments, aside from the one investment of using what little money you have to pay debts, I think *they* should be consulted. It is not only that you want to succeed in eventually paying all you owe, but it is that you may honor the Master, not only at some future time, but even now. You may meet sickness or death, and be absolutely unable to pay these debts. How shall you honor the Master meanwhile — that is, before you are able to pay your debts? What ought a Christian to do in such cases? It is true, you must have a little money for necessary expenses; for if you decide it best to hand over *every* dollar to your creditors as fast as you earn it, it might so cripple your abilities that you could not work to advantage. Now, whether the amount is large or small, I would try to do it on a basis something like this: I would first sit down with pencil and paper, and make a neat and accurate list of all I was owing my friends; then I would go to them personally, or write them, and tell them just how the matter stood, and ask permission of them to use what little money I might have, in such ways as might seem best and wisest. If you are owing these friends money that ought to be paid, the money you have in your possession is theirs and not yours. If you can make an arrangement with them to wait on you until some set future time, all well and good. Then you can meet them and look them in the face without fear or shame, and without the recollection of broken promises. My experience has been, that there are very few people in the world who will not willingly agree to wait for money, with a reasonable expectation; and especially is this the case where you mutually agree upon a fair rate of interest, and keep the interest paid. Where it is impossible to pay the debt, it is oftentimes within the debtor's power to pay the interest — say yearly, semi-annually, quarterly, or monthly, as may be agreed upon. Now, even if this payment *is* only a few cents it is a sort of guarantee that you mean to be straightforward and honest. It goes a very great way toward giving confidence. I would advise one who is in debt, as you say you are, to sacrifice a great deal, and go to a great deal of trouble to pay this matter of interest promptly; and it has often seemed to me as if God took pleasure in honoring a man who pays interest promptly, by helping him very soon to pay the principal also. This matter of paying interest seems to get one who is down, upon his feet again. If he is not paying up the principal as he agreed and expected to do, he is doing the next best thing. A dollar is a small amount of money, and some may laugh at me when I say that, if I were you, I would not even subscribe for a bee-journal until I had the consent of my creditors. There may be several other investments you would like to make. Put them down in writing, submit them to your creditors, with the reasons you have given me; and if they say, "All right, old fellow, send for your bee-journal," then you can do it with a clear conscience. Just try it and see how much happier and light-hearted you feel at once. The idea is, that you have obtained an honorable discharge from the debt for the time being, and no one whom you are owing can say, as you take your periodicals from the office, "I think Mr. X. Y. Z. had better pay me what he is owing me before he spends money in that kind of way." When you want to go to prayer-meeting, and are called upon, as God calls upon us all, to stand up and testify for the Master's sake, how much better you will feel when doing it, if you have made honorable arrangements for all these outstanding debts! It seems to me, dear friend, you do not know how much it helps the world to have faith in Christianity and in a Christian profession, to have each follower of Christ attend to these little things—these small items.

You say you were once a professor of religion when you were young. I suppose you know, my friend, that the danger is tenfold greater that you go back, when you have once wandered away from the fold. The horse that has run away once is very apt to run away again; and after he has run away three or four times the world generally settles down to the conviction that there is no cure for him—he is always nothing but a runaway horse. I do not say this to hurt your feelings, but I say it to warn you of the very great need there is of being careful in your second start. It is not at all impossible for one to repent and come back afterward, when he has wandered away, or even if he has repeatedly deserted his Savior. It is only a simple matter of the will. By dallying with sin, the will power becomes weakened; and when temptation comes we are apt to think it does not make very much difference if we go back to our sins, and then at some future time make still another start; and by and by the poor deluded victim of Satan does not care to try any more — he gives up to his fate; therefore, one who has once slipped back, and starts again, must recognize that it is of the greatest importance to watch every little thing, even small trifles like taking a dollar to subscribe for a bee-journal. The laws of God and the laws of our land are terribly severe on those who take what belongs to their neighbors, without rendering a proper equivalent. Our text says, "Thou shalt love thy neighbor as thyself;" and the law of our land says, "If you do not respect the property of your neighbor, you shall be severely punished."

Last Sunday I met two of our neighbors in jail, who were bowed down with grief. One of them is the father of a little family. He was sentenced to thirty days in the workhouse, in a neighboring city, and a fine besides. What do you suppose it was for? The two men together stole four chickens of a neighbor. They were drawing this neighbor some wood, and the chickens were very tame, and came so near where they were unloading that it was an easy matter to pick them up. They took two apiece, and took them home; but afterward their consciences troubled them so much that they went to this neighbor and paid him to his full satisfaction for the fowls. The matter was supposed to be all pleasantly settled. Not so, however. A third party heard about it, and had them arrested. The fact that they had settled for their folly, and paid over the cash for twice what the fowls were worth, did not alter it. They were in heart, and before God, guilty of stealing, and the law did not release them, even if they were sorry afterward, and settled it. Now, forgive me if I cut close. Suppose these two men had, by entreaties, urged this neighbor to trust them for a few days for the fowls, but afterward, finding themselves cramped for money, had put it off from time to time, and finally never paid him. Suppose, too, that when he was importunate for his money for the chickens the men should get angry, and tell him flatly they would not pay it until they got ready, and to help himself if he could. In this latter case the law could not touch them—that is, in most States at least, they could own considerable personal property, exempt from any claims the creditors could make. If my knowledge of the law in the above matter is at fault, please excuse it; but I think I have it substantially correct. In one case the owner of the fowls is wronged as much as in the other, or a great deal more; because, in the first case, he lost no money at all—in fact, he got a big price for the fowls. In the latter case he never gets any thing, and perhaps spends a good deal more time in trying to get it than the fowls are worth. I have dwelt on this, because I wish to have the friends all understand, especially the younger ones, what a grievous thing it is to incur a debt one can not pay.

Perhaps I might touch on another phase of this matter of debt. There are those who deliberately contract debts knowing there is very little or no prospect of being able to pay them. The law can punish a thief, but it can not punish this class. I believe, however, that this latter class is comparatively small. I have never met many people who did not fully intend to give value received when they made purchases; but even with honest intentions, we often harm ourselves and harm our neighbors. The class of people who do these things are often those who are bright, cheerful, and hopeful; and, my good friend X. Y. Z., I hope you will excuse me for saying that I feel almost alarmed to hear you say, "My prospects are at present very flattering for the coming season." May be they are; but judging from past experience, I believe I would rather you felt as if they were the other way. I believe I have known young men to get along better when they looked at the future something like this: "It is a sad truth, that the prospect before me is not flattering. If I succeed it will be only by earnest, faithful, hard work, early and late; therefore I have no money to spend on amusements. I can not afford to stop and listen to gossip. I must be at work by daylight, and work while the daylight lasts, or I shall never be able to meet my honest obligations." One who feels this way will come out all right.

In regard to taking queens of you in June, 1886, we have been obliged to tell our friends that we dare not promise to take queens so long ahead. We don't know what the future is. I should fear to make promises six months ahead, which it may trouble us to keep. Another thing, friend X. Y. Z., it would be, at least to a small extent, encouraging you in adding to the debts you have already. It is putting it off a long time ahead, I know; or, in other words, you have a good while in which to make the money. But this very thing I fear: A good many who, like yourself, have become involved, often seem to think if they can get an accommodation for a *long* time it is all right; but when the long time has expired, nine times out of ten they find themselves just as badly off, or worse, than when the debt was contracted. You have come to me for advice, and I have spoken my convictions very plainly and fully. Dear friend, I would not go in debt to the extent of one dollar, even if you can have six months' time in which to pay it, if I were situated just as you are, and wanted to pay up my debts and follow my Savior. The concluding part of your letter is excellent, and the spirit of it is right.

There is a part of your letter, back a little, that I wish to refer to. You say you are going to make restitution "just as fast as the Lord will let you;" that is, if he prospers you, you will pay your debts; but if he does not, how can you? I know there are two extremes in both ways here. Unless the Lord gives you health and strength you can not earn any thing at all, so you are dependent upon him. But we are all of us prone, I am sure, to get into a way of thinking, when we fail of doing what we know we ought to do, to give up and content ourselves by saying, "The Lord did not see fit to help me do what I wanted to do," when the truth is, we have not made proper use of the blessings already given us without stint. Those who have once gone astray, and started back again, are specially apt to get into this way of reasoning. I believe it is very seldom that God does not provide a way in such matters as this, where the one who is striving to follow him is in dead earnest in the matter. What I mean by "dead earnest" is to be self-sacrificing, careful, sober, and wise. In our zeal to pay our debts we might overwork ourselves, and thus defeat the object in view. But I do not think this oftens happens. People tell me I am overworked, a great many times, and doubtless they think so; but it is not true. It *is* true, however, that I waste my strength and energies, oftentimes, on things comparatively trifling and unimportant, and then I can not do the important work that ought to have taken the place of these.

Now, then, to the last point before us. How shall friend X. Y. Z. get a bee-journal, or several bee-journals, when they would no doubt be worth several times their cost to him? Candidly, dear friends, I do not know. I would give him GLEANINGS without charge, most gladly and willingly, were it for his best spiritual good that I did so. Yes, I would give him a hundred copies if I were sure it would result in building up Christ's kingdom. But my experience in gifts in this way has not been pleasant. I can look back through the years, and see a great many times when I tried to make the path easier for some poor sinner, by gifts of money or other things that he had not earned, that I made it harder because I relieved him a little from the responsibilities that God wanted him to bear. I dare not do it any further. I have asked God to give me money that I might use it in saving souls. The money has come sometimes bountifully, and I have used it, as I thought, wisely; but it has almost always done harm unless I used it as a reward for fair and honest work. Friend X. Y. Z. has not asked me for any gift, it is true; but this thing had to be considered: What will be the best course for our boys and girls—yes, for our sons and daughters, in helping them to build a good Christian character? My reply is, that I know of no way but to let them earn the things they want, by the sweat of their face—by the exercise of their minds and muscles. I said I did not know of any way our friend could get a bee-journal, under existing circumstances. What I meant was, that I did not know any way except the one I first pointed out—get the consent of his creditors before he uses money belonging to them. I did not mean to say that *I* would not trust him for GLEANINGS for six months or a year, because I will gladly, if he wishes me to. Yes, he need not pay for it for five years, if he thinks best to do that way, after what I have said. I meant simply this: If he wants my advice, and wants me to stand in his shoes, to use a common expression, my advice for him is, not to run in debt one copper for any thing; get the consent of his creditors in the way I have marked out, and then pay cash down for every thing he buys, or else go without it. The accumulation of debt has made him enough trouble already. Don't have any more of it; and if there are other brothers or sisters situated in like circumstances, I say the same to them. Look at it as you look at any other temptation that Satan may hold before you. Say to him, "No, sir; get thee behind me, Satan," and then *make* him get behind. Do the same with other besetting sins, and ask God to help you to do it; and if a happy, useful, prosperous Christian life does not open up before you, then I shall be much mistaken.

Our text says, "Thou shalt love thy neighbor as thyself." Well, dear friend, suppose you were owing a neighbor money which you have promised him, and failed to get. Suppose, too, he needs it badly. You know it is not unlikely that he may be failing in his promises because you have failed in yours. *His* good name must suffer because he has been forbearing and patient with you. Well, now, under such circumstances suppose when you have some money that you might pay him, you should, instead of handing it over to him, use it for something you didn't like to give up yourself. Do you not see how very far you would be from obeying the spirit of the text? Do you not in reality act as if the text read this way: "Thou shalt love thyself better than thy neighbor, and under all circumstances let *self* come first when you are obliged to choose between the two?" The spirit of the text is to the effect that we should consider our neighbor's own good or his best good, just as much as we should consider our own good. But when it comes to choosing who should be accommodated, yourself or neighbor, when the accommodation is due him, and is *not* due you, the obligation on your part becomes a very sacred one. If I owed a neighbor some money, and he needed it, and wanted it, I think I would do without a bee-journal, and, in fact, almost every thing else, until he willingly granted me permission to delay payment.

I do not by any means think it wrong for people to borrow money, or to borrow things. We confer great favors on our neighbors by borrowing things they want to lend, and many of us have money that we are very glad to loan to somebody who can make use of it so that it will be a mutual accommodation. Such transactions are right and proper. But the great important thing for a Christian to do is to keep on safe ground, so that he can not only pay the interest promptly, but pay the principal, say twice over, any time it may be asked for, and that, too, without any great sacrifice. I have sometimes invoiced myself something like this: "I am owing, say, one thousand dollars, or paying interest on one thousand dollars, borrowed money; but I own property that would sell readily right here at home, without much effort or time, for ten thousand dollars; therefore I can not in any case be very badly cramped." But suppose the circumstances should show like this: "I am owing one thousand dollars, but my whole effects would not probably sell for moret han four thousand, if I were obliged to sell." Now, the above is not so bad; but still not what I should call really safe ground. I do not like to be in that predicament; and when our personal effects are not all together worth more than twice what we are owing, we are in great danger. Sickness, decline in values, fires, robbery, or things of that sort, are liable at times to place us where we can not show such a record before the world as every follower of Christ ought to show.

Now, why can we not be happy and satisfied and contented with the things we are able to buy, without running deeply into debt? Why, almost anybody will tell you that the satisfaction and real enjoyment is in being out of debt — or, at least, in owing so little that you shall never be distressed in paying it, should it be suddenly wanted. Has it ever been proven to you that happiness necessarily follows good speculations, or doing a large amount of business?

Now, friends, what is to be gained, after all, by running risks, and even succeeding in making good speculations? Is the good to be secured in any measure to be compared to the danger? What shall it profit a man if he gain the whole world, and lose his own soul? May God in his great and loving mercy watch over you, friend X. Y. Z., and give you wisdom; and may he bless these words that have come from one who is but a weak brother after all, not only for your use, but to the multitude of others like you whose eyes may fall upon this Home Paper. May he teach you the way to that only real enjoyment and peace; and may he in the end lead us all to the golden gates of eternal life, where we shall comprehend and understand the very, *very* great importance of trying, at all times to love these neighbors all round about us as we love ourselves.

Be diligent that ye may be found of him in peace, without spot, and blameless.—II. PETER 3: 14.

PEAT INSTEAD OF MOSS FOR COVERING SEEDS.

SINCE writing "What to Do, etc.," for this issue, our gardener tells us that dried and sifted peat will answer nearly or quite as well as the dried and sifted moss that Peter Henderson recommends.

NAMING THE SEEDS.

THE *Rural New-Yorker* sends out a kind of field corn which they have labeled "Angel of Midnight." Truly, the *Rural* folks are booming with enterprise and "go ahead." They send all their patrons a good lot of nice seeds, any way.

THE HEAT OF OLD MOTHER EARTH, VS. STEAM HEAT.

OUR poultry-house, warmed by steam, gives us, during this zero weather, one egg a day—perhaps a dozen hens. A neighbor gets nine or ten a day from thirty or forty fowls. When I asked him how it came that they laid in the depth of winter, he said they were in a cellar under his barn, built on a side-hill. The heat of old Mother Earth keeps them warm. Are we all of us making the best of such natural facilities for warm underground quarters for our stock? The heat of the earth, when we once get fixed so as to utilize it, is cheaper than fuel.

A NEW SILVERHULL BUCKWHEAT.

PETER HENDERSON mentions, among his novelties for 1886, European silverhull buckwheat. We wrote him for particulars in regard to it. Even if it has but a *little* advantage over the old kind, we bee-keepers must have the benefit of it. Here is what he has to say in reference to it:

> This is a most desirable acquisition for this country, and it has done remarkably well the past two seasons as far north as Northern Vermont, where the seed we now offer has been grown expressly for us. It may be depended upon to ripen in any thing like a favorable season from ten days to two weeks earlier than the native American silverhull or common buckwheat. Berry is small, with rounded corners, and of a beautiful silver-gray color; grows to the uniform height of three feet, standing up well and branching luxuriantly. Straw, a deep rich wine color when ripe. It is a heavy yielder and thus far is not so easily affected by drought and frost as other buckwheat.

We can furnish the seed in five-cent packages, or in larger quantities, at about three times the price of the old silverhull. We shall give it a thorough test this coming year on our honey-farm, and report.

DOES IT PAY TO HAVE AN IMPORTED QUEEN IN YOUR APIARY?

THIS question often comes up, and I should be glad of the experience of honey-producers in the matter. Do you get more honey from Italian bees, say only one or two generations from Italy, than from stock bred four or five years in our own country? Selecting for many generations the best honey-gatherers to breed from would probably improve on the stock received direct from Italy; but, how has it turned out in practice? A few years ago it was decided that bees from stock not very long from their native clime gathered more honey than Italians that had been a long time on our shores. Let us have some facts from actual experience.

OUR CATALOGUE OF VEGETABLE SEEDS, PLANTS, HONEY-PLANTS, ETC.

WHEN our last issue went to press, the type was already up for this catalogue, or nearly so; but we have been so crowded to get off promptly the circulars and price lists for the bee-brethren, that our own was obliged to stand still and is standing still yet. We hope it will be out, however, within the next ten days. Besides seeds and plants, it includes also supplies for market gardeners, and some supplies for the poultry business; also galvanized wire cloth for carp-ponds, fruit-dryers, etc., etc. Our facilities for getting the above goods at a low price are such that we believe we confer a favor in handling them; for by buying in large lots as we do, we are enabled to give prices on such things at retail, heretofore unknown.

HATCHING CHICKENS IN JANUARY.

THERE, I have gone and counted my chickens before they are hatched. It is one of our nice Brahma hens that is going to do the hatching, and she is under one of the benches in the greenhouse. When I put her there she would not sit down on her nest; but after I took thirteen eggs out of my pocket, and placed them beside her, she took her bill and pushed them under with great satisfaction, and sat down as motherly as one could wish. When it came breakfast time, however, she got into one of the boxes of lettuce plants, and don't you believe she made them fly? Some of them must have hit the glass overhead; and after she did the same thing next day, Mr. Weed, the gardener, wanted to have her discharged for bad behavior. We didn't, though; we just put some poultry netting around her, and now she sits in one corner, and sits equal to any new-fangled incubator. She started New-Year's day, so the chickens ought to hatch out on the 21st. In our next number I will tell you how many she brings out. I presume likely Huber will be able to count them.

SOLAR WAX-EXTRACTORS.

OUR friend Arthur Todd, of Germantown, Pa., sends us a copy of the *Bulletin de la Societe d'Apiculture de la Somme*, one of the most enterprising of our foreign exchanges, dated July and August, 1879, containing a picture of a solar wax-extractor, made by putting a pane of glass over the top of a machine that closely resembles Dadant's uncapping-can; so it seems that solar wax-extractors have been a good many years in use. And, by the way, I do not know why an uncapping-can might not answer excellently, with a circular piece of glass dropped down in the top a few inches, and then the whole machine inclined at the proper angle toward the sun. If the inside of the upper can is kept scoured with whiting it will be an excellent reflector. I would drop the piece of glass down a few inches, to be out of the way of the wind a little more. Please let us have reports from this arrangement. Meanwhile we extend thanks to friend Todd, who was, we notice, an apicultural delegate to the Paris Exposition in 1878.

THE NECESSITY OF LARGE PROFITS ON SEEDS OF DIFFERENT KINDS.

WE oftentimes wonder why seedsmen pay, say a dollar a bushel for a certain kind of seeds, and retail them out for two or three dollars a bushel. One reason why there must be large profits is this: Every seedsman wants to have enough seeds to supply all demands; but in order to do this there is no way but to buy a good deal *more* than enough; and as it is not advisable to use many seeds more than one year old, the surplus remaining on hand must be burned up, or sold at an insignificant price compared with first cost, or be fed to stock. Almost every year we have to throw away seeds of spider plant and figwort that cost us a good many dollars, or else face the other dilemma of being unable to supply the demand.

A BRANCH SUPPLY - HOUSE FOR THE FRIENDS IN THE SOUTH.

FOR years there has been much talk about some arrangement whereby our friends in the South might have their supplies, without paying the enormous express and freight charges that they have had to pay for years back. For instance, if a man wants ten pounds of foundation, and wants it right away, there is no way he can get it very well by mail, freight, or express, without paying about half its worth to him in the way of charges—that is, providing he deals with us, and a great part of our trade comes from the Southern States, especially the latter part of winter and early in spring. It is true, we have supply-dealers in the South, whom I would by no means forget; but none of them have ever felt like keeping the extensive and varied assortment that we keep. Well, for months past we have been corresponding with Mr. J. M. Jenkins, of Wetumpka, Ala., and he has recently paid us a visit, and looked the whole matter over, and we may say the arrangement is now completed. The goods are to be shipped to friend Jenkins by the carload, so that the freight is really but a small item. Where he has customers near to us he will have the orders filled from our place, and *vice versa*, and he will furnish *nearly* all we advertise, at our prices. Friend J. is not only a bee-keeper, but he is a railroad man, and has been for many years perfectly conversant with the whole matter of freights, north and south; and as he has also served as express agent, he is at home in regard to all express business. Furthermore, he is a man held in high estimation by all railroad companies in his section, and many of the managers of the different companies have expressed their willingness to assist him in the enterprise. Friend J. being a railroad man, has, by the assistance of other railroad officials, arranged to secure a wonderfully, low rate of freight from our place to his. He manufactures Simplicity hives from southern white pine, so as to sell them at our prices in Wetumpka.

Now, then, if we can not help in this great matter before us, of bringing about friendly relations, and especially friendly *business* relations, between the North and South, it will be funny.

TOBACCO COLUMN.

TOBACCO AND HEART DISEASE.

THERE is one evil, and I think one of the greatest, yet I have never seen it in print. That is, sudden death from heart disease; but I say, tobacco disease. These deaths have increased a hundred fold since my young days. I am over 81 years old; 70 years ago I saw but one smoker, and he an old man or old woman, where we now see a thousand among the same number of people. Young men commenced smoking about ten years after; and about forty years later I saw, for the first time, little boys smoking.

We had no matches nor cigars till about 1830, hence smoking was more difficult. I never saw, in any newspaper of that date, an account of any children falling dead, although I read several weekly papers, but now I see accounts of several boys and girls who dropped dead at the age of about 14 or 15 years old. This evil increases as smoking increases. If the increase of smoking is as great for 50 years to come, I believe the sudden deaths will be 1000 times as great. And why? Because these children now smoking will raise children who will inherit the tobacco poison from them. Many infants in these days inhale this poison into their tender lungs the first days of their lives, from a smoking father, in a tight room. Since 1830, cook-stoves have been introduced; hence smoking in a shut-up room is much harder on an infant in the cradle, and all others, than it was when there were none but a few old people who smoked, and that in a chimney-corner, where nearly all the poison would go up the chimney.

I find that railroad offices are filled more with tobacco poison than elsewhere, and officers frequently drop dead, one lately in Cincinnati. No railroad officer should be allowed to smoke. It divides their attention, addles their brains, and hinders sober thoughtfulness; hence the danger of life and limb, so frequently of late, on railroads.

Plainville, O. ISAAC LARRANEE.

HOW THE "DOSE" CURED.

I did not think to explain myself. I used tobacco for about 20 years. I quit 4 years ago this fall. I have never used any since, and never expect to again. I am now 51 years old. I have read the "Dose," and it is the best I have ever seen. I will do all that I can to stop the use of tobacco. I will lend the Dose to others to read. I have been handling bees for five years. I have never had more than 20 colonies at one time. I have sold down to four this winter. I don't think this country is very good for honey. There has been but one good year since I came here. LEWIS N. COOPER.

Tehama, Cherokee Co., Kansas, Dec. 24, 1885.

I hereby promise to pay for the smoker, whatever the price may be, if I ever am weak enough to chew or smoke any more tobacco, or use it in any other form. J. C. PARKS.

Scottsboro, Ala., Nov. 16, 1885.

I have quit the use of tobacco, after five years' use; and if you think me entitled to a smoker, send me one; and if I ever use the weed I will pay you for it. I take a deep interest in bees.

WARREN KEY.

Victory, Carroll Co., Ga., Nov. 30, 1885.

AN HONEST OWN-UP FROM ONE OF OUR BOYS.

I returned home from Sioux City last Monday; that is why I failed to answer your letters. I was gone two months. The 75 cts. is for the smoker you gave me for quitting tobacco. I have broken my pledge. I smoked a cigar to ease my toothache while in Iowa, but it makes no difference. I broke my pledge. However, I have quit again. Don't put me in the Tobacco Column this time until I see if I can hold out. REESE POWELL.

Mineral Point, Wis., Dec. 18, 1885.

May God bless you, friend Reese, for your truthfulness, even though you *have* broken your pledge. You have fulfilled your promise to the very letter, and I am very, very glad to hear you say you are going to try again. I have disobeyed you a little in putting this in print; but since I do it for the encouragement of lots of other boys who are looking on, I am sure you will excuse me. I believe if I were you I would bear the toothache rather than take the risk of starting the old habit again. May God bless you, my young friend, and help you to hold out.

CONVENTION NOTICES.

The North-Eastern Ohio and North-Western Pennsylvania Bee-Keepers' Association will hold its seventh annual convention in Meadville, Pa., Wednesday and Thursday, Jan. 20 and 21, 1886.

New Lyme, O. C. H. COON, Sec.

The next meeting of the Maine Bee-keepers' Association will be held at Skowhegan, Maine, Jan. 19, 20, 21, 1886. WM. HOYT, Sec'y.

Ripley, Me.

The Bee-Keepers' Association of Hancock Co., Ohio, will meet in Findlay, Sat., Jan. 23, 1886.

Stanley, Putnam Co., Ohio. S. H. BOLTON, Sec.

The Twelfth Annual Convention of the Champlain Valley Bee-Keepers' Association will be held in the basement of Town Hall, Middlebury, Vt., Thursday, January 21, 1886. A general invitation is extended to all. R. H. HOLMES, Sec.

Shoreham, Vt.

The Indiana Bee-Keepers' Association will meet in Indianapolis, Jan. 21, at 1 P. M., in the State Board of Agriculture Rooms, opposite the new Statehouse. We should be pleased to have all meet with us, and hereby send an earnest invitation to come. JONAS SCHOLL, Pres.

Lyons Station, Fayette Co., Ind.

The Eastern New York Bee-Keepers' Association will hold its Annual Convention in Agricultural Hall, Albany, Tuesday, Wednesday, and Thursday, January 26, 27, and 28, 1886. There will be three sessions each day after the first. First session Tuesday, 26, at 2 o'clock P. M. All interested in bee-keeping are requested to attend, and bring apiarian supplies for exhibition. The programme will consist of essays on important subjects, discussion of questions of interest, etc.

Halfmoon, N. Y. C. W. PHILO.

The North-Eastern Michigan Bee-Keepers' Association will hold its fourth annual convention, Wednesday, Feb. 3, in the Council rooms at East Saginaw, Mich. The Sherman House, one block from place of meeting, will entertain those present, at $1.00 per day. Saginaw folks are working hard to make every thing pleasant for those from abroad. Let us turn out and show that we appreciate their efforts. W. Z. HUTCHINSON, Sec.

Rogersville, Mich.

The Seventeenth Annual Convention of the New York State Bee-Keepers' Association (formerly North-Eastern) will be held in Rochester, N. Y., on 16th, 17th, and 18th of Feb., 1886. This will be one of the largest meetings ever held in the State. A large number of our most experienced bee-masters will take part in the discussions, and several essays will be read from a number of our most practical men throughout the country. The programme is complete. If you are young in the work, you can not afford to stay away. If older, you may give some good hints, if you get none.

We want a good display of all kinds of supplies and fixtures. We have a room on purpose for exhibits, and any goods sent to the secretary, in care of the "National Hotel," Rochester, N. Y., will be placed on exhibit and either sold or returned to the exhibitor, as directed.

Reduced rates at the hotels have been secured, also rates on some of the railroads. All will have to pay full fare one way; return ticket at ½ fare, by presenting certificate from the secretary, who will furnish them on application. We want an active vice-president in every county in the State. Please name or send the name of some one for your county.

F. C. BENEDICT, Sec.
Perry Center, N. Y. L. C. ROOT, Pres.

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was $40.00, but we will now sell it at half price, or $20.00.

Also one exactly like it, owned by W. W. Bliss, of Duarte, Los Angeles Co., Cal. There is nothing wrong with these mills, except that the rolls are of smaller diameter than those we now make, in consequence of which they do not make quite so thin fdn. right in the middle of the rolls as those made now with rolls of a larger diameter. They will, however, roll narrow sheets equal to any, and will roll sheets a foot wide; but when of so great a width, the center is a trifle thicker, as explained above.

A. I. ROOT, Medina, O.

GOOD NEWS FOR DIXIE!
SIMPLICITY HIVES,

Sections, Extractors, Smokers, Separators, &c., of Root's Manufacture, Shipped from here at ROOT'S PRICES.

Also S. hives of Southern yellow pine, and Bee-Keepers' Supplies in general. *Price List Free.*

18-INCH GEM PLANER
FOR SALE, FOR $70,00.

Franks' make; used about a month, and warranted in good order. Address E. Y. PERKINS,
3tfd Jefferson, Greene Co., Iowa,

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—The market remains quiet, and does not show much activity. Since September 1, 1885, our receipts of comb honey have exceeded 11,500 crates, and to-day we have on hand about 1500 crates. Buyers and jobbers who bought heavily last fall have not disposed of their stock as yet, which causes the present state of the market. However, we expect a fair demand during February and March. We quote at present: Fancy white 1-lb. caps, 13@14c: 2-lb. caps, 11@12c; fair and off grades, 1-lb. caps, 11@12c; 2-lb. caps, 10@10½c; buckwheat, 1-lb. caps, 10@11c; 2-lb. caps, 9@10c; extracted, clover and basswood, 6½@7½; buckwheat, 5@6c.

THURBER, WHYLAND & CO.,
Jan. 21, 1886. Reade & Hudson Sts., New York.

NEW YORK.—*Honey.*—The market for comb honey continues dull and inactive, and prices are ruling lower. The present cold weather, however, should it continue, may improve trade in a short time. We quote as follows:

Fancy white comb, 1-lb. paper cartons,	13@14c.
" " " " glassed or unglassed,	12@13c.
" " " 2-lb. glassed,	9½@11c.
" " " " unglassed,	11@12c.
" Buckwheat, " " glassed,	9c.
" " " 1 lb. glassed or unglassed,	10@11c.

No change in extracted. *Beeswax*, pure yellow, 27@28c.

MCCAUL & HILDRETH BROS.,
Jan. 12, 1886. 34 Hudson St., cor. Duane St.,
New York.

CHICAGO.—*Honey.*—Sales are quite good at present in both comb and extracted honey. Comb brings from 15@17c, and from 14@15c. The stocks here are very light, and honey is wanted. Shippers should see to the loading of honey in a through car to destination. *Beeswax*, 24@26. Extracted honey, 6@8c.

R. A. BURNETT,
Jan. 20, 1886. 161 So. Water St., Chicago, Ill.

MILWAUKEE.—*Honey.*—The market is without material change since my last report. The supply of choice white comb in 1-lb. sections is not large, and I can encourage shipments of such. Quote white 1-lb. sections, 15@16c; large sections or dark, 13@14c; extracted, in barrels or kegs, white, 7½@8; colored, 6½@7c.

A. V. BISHOP,
Jan. 21, 1886. 142 W. Water St., Milwaukee, Wis.

BOSTON.—*Honey.*—Best 1-pound sections, 14@16; best 2-pound sections, 12@14. Slow sale. No demand for extracted.

BLAKE & RIPLEY,
Jan. 21, 1886. 57 Chatham St., Boston, Mass.

CINCINNATI.—*Honey.*—There is nothing new to report on the market for honey and beeswax. An exceedingly slow demand for all kinds, and low prices, make matters very unsatisfactory. Demand would not be stimulated by lower offerings. No change in prices.

CHAS. F. MUTH,
S. E. Cor. Freeman and Central Avenues,
Jan. 26, 1886. Cincinnati, Ohio.

CLEVELAND.—*Honey.*—The market has not changed materially since Jan. 1st, except it exhibits the usual stagnation prevalent at this season. The stock of new 1-lb. sections of white is very small, and prices 14@15c; 2-lb. are in better supply, but very slow at 13@14. Other descriptions are entirely unsalable at any price. *Beeswax*, very scarce at 22@25.

A. C. KENDEL,
Jan. 20, 1886. 115 Ontario St., Cleveland, Ohio.

ST. LOUIS.—*Honey.*—Our honey market is very dull. No inquiry for any kind. Prices normal. Southern, in bbls., 5@5½c. Northern, in cans, 8½@9c., retail. Comb honey, white clover, held at 15@16c, in 1-lb. sections. Dark not wanted at any price. *Beeswax*, 22½@23c; not much arriving.

Jan. 12, 1885. W. T. ANDERSON & CO.,
104 N. 3d Street, St. Louis, Mo.

DETROIT.—*Honey.*—No change in Detroit honey market. Best white comb honey, in 1-lb. sections, 15 cts. Dark, almost unsalable. Extracted selling in a small way from 10 to 12 cts. per pound. *Beeswax*, 25@27c, wholesale. The above quotations in honey are from my actual sales. M. H. HUNT.

Bell Branch, Mich., Jan. 22, 1886.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this deparment, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not. **CLEMONS, CLOON & CO.,**
15 7db **Kansas City, Mo.**

SECTIONS CHEAPER THAN EVER.
THE "BOSS" ONE-PIECE SECTION.

PATENTED, JUNE 28 1881

Patented June 28, 1881.

Bee-keepers will find it to their interest to send for our price list, just issued, before ordering their sections for 1886. We have our machinery in first-class order, and can turn out more sections per hour than other manufacturers in the United States.

NOTES FROM THE BANNER APIARY.

NO. 74.

HOW SHALL WE MAKE THE MOST PROFIT?

OUGHT not Mr. Doolittle's heading to his article, on page 13, to have been, "Few or many *bees:* which?" instead of "Few or many *colonies:* which?"? It is *bees*, not *colonies*, that overstock our fields. Mr. Doolittle discusses *overstocking*, but not one word in regard to his subhead, "Shall we have a few bees in many hives, or many bees in a few hives?" You know Mr. Heddon, Mr. Dadant, and myself, have been discussing "Small vs. large hives," and when I read Mr. Doolittle's two titles I was, of course, interested, and read the article eagerly, only to be disappointed in not finding a word upon the subject. I fully agree with Mr. Doolittle, however, in thinking that so many bees can be kept in an area that the profits would be greater were a less number kept; but whether they shall be kept in few or many hives, is entirely another question. In my opinion, we lose when we go *too* far in either direction in the size of hives. I would have a hive of such a size that a queen of average prolificness would *fill* the combs with eggs, and *keep* them *full* of brood, during the fore part of the season; but as this question has been discussed at length in the *A. B. J.*, it will hardly be advisable to go into it here. The large amounts of grain, fruits, or vegetables, that have been produced upon an acre as the result of high manuring and much labor, are not proper comparisons for the profitableness of the raising of large amounts of honey from only a few colonies. "Circumstances alter cases," and these cases are entirely different. All products are the result of labor and capital; and not only in bee-keeping, but in all industries, we should strive to secure the greatest profits with the least expenditure of capital and labor. Where "intensified" farming, as it is called, is practiced, is usually where land is high. The largest part of the capital is invested in land, hence it follows that labor is used freely in order that the immense amount of capital may be utilized. But let us go "out west," where "Uncle Sam" will "give us all a farm;" will "intensified farming" pay there? No. When the settler has put one acre into crops, with ordinary care it will pay him better to put the same amount of labor upon another acre (that costs next to nothing), rather than to bestow it upon the first acre. "Circumstances alter cases;" and which is the more expensive factor should be well considered, not only in farming and bee-keeping, but in *all* industries.

The question is something like: Here is an area of honey-producing flora; how shall we secure the nectar, with the least expenditure of capital and labor? or let us put it in a little different form. A man wishes to engage in bee-keeping. He has an unlimited amount of capital and labor; in what proportion shall he combine them? In bee-keeping, capital is the less expensive factor, and should be substituted for labor when possible. As to *how many* bees should be kept in one locality, is a question of overstocking, and is a very difficult one to decide; but when the question is one of many bees and little labor, vs. few bees and much labor, the former is to be chosen.

There is, however, another phase to this question. Many bee-keepers are limited as to capital, and it is impossible for them to secure so many bees as could be kept to an advantage in their locality; such bee-keepers will probably find it to their advantage to employ all the labor *necessary* to secure all the honey that their bees can gather.

I agree with you, friend Root, in advising us to keep our colonies strong, *except* that I would have them strong per *comb;* or, to be more explicit, I see no advantage in *large* colonies, but I want a large number of bees per *comb*.

EIGHT OR TEN FRAMES: WHICH?

As Mr. Buchanan, on page 8, brings up some points that have not been touched in the discussion upon this subject in the *A. B. J.*, it is with pleasure that I reply to them. He must have put some very poor workers into the 8-frame hives the first year, to have received no more surplus, and then had to feed them the next spring. Had he received more surplus from the 8-frame hives, and *then* had to feed the bees, it would have appeared reasonable; but the statement as now given appears to prove *too* much. If there were more bees in the 10-frame hives, then they should have eaten more honey, and needed feeding, just the same as the bees in the 8-frame hives. If there were no more bees in the 10-frame hives, why should they have stored more honey?

It is true, as Mr. B. says, that bees in small hives are more likely to need feeding; but the reason is, that the brood-nest occupies the combs to the exclusion of the honey, which is, of necessity, placed in the surplus apartment. My comb honey, some part of which the contraction method forced into the sections, netted me this last year about 16 cts. per lb., and was replaced in the brood-nest with sugar syrup at a cost of about 5 cents per lb. It is true, that Mr. Heddon is selling his fall honey at 7 cents; but I believe he has explained why he raised extracted honey this year. It was because he had a large stock of empty combs, and wished to utilize them. When extracted honey is raised, there is, of course, but little advantage in contracting the brood-nest; at least, so far as pieces are concerned; but when a bee-keeper finds it necessary to substitute sugar for honey in the fall, in order to winter his bees, it is a *great* point. It may not be advisable for farmers or careless people to use small hives; perhaps they had better not keep bees at all; at least, so far as profit is concerned; but this question is one of considerable importance to the professional bee-keeper.

It is true, that bees in small hives are more likely to swarm; hence small hives are not advisable, for *this* reason, for those who wish little or no increase. The question of swarming vs. no swarming is too large to be handled in this article. I will say this much, however: I have (with the exception of one season, when the harvest came early and was cut short early) secured more honey from a colony (and its increase) that swarmed, than from one that did not. If swarming could be prevented *entirely* it might be an advantage, as an apiary could be left to itself part of the time; but when part of the colonies swarm, and some one must be present all of the time, they might as well *all* swarm.

Mr. B. speaks of the trouble of contracting the brood-nest, disposing of combs removed, returning them again when needed, cost of sugar for feeding, *preparation and cost of feeding*, and the lessened room above the brood-combs for sections. The only valid objection is the one I have put in italics. It is no more work to remove the combs than it would be to remove the same number of combs from any hive when running for extracted honey. The contractors, or "dummies," not mentioned by Mr. B., cost something, about 10 cts. per hive; that would be about one cent a year per hive. It takes no longer to extract the honey from these combs than from any. Extracting-combs have to be stored away for winter, so we will store away these where they are to remain all winter. In both instances the combs must be replaced in the spring. Sugar does not cost so much as the honey that it is used to replace. When every thing is conveniently arranged for feeding, the cost of preparation and feeding, including feeders, will not exceed 5 cts. per hive. Can we not bear this expense, if it will enable us to successfully winter our bees, even if there were no other advantages? The lessened room above the brood-combs is no objection when the bees are crowded for room.

You, friend Root, say that the greatest objection to an 8-frame hive, aside from those given by Mr. B., is, that it could not be made interchangeable with 10-frame hives, when made on the Simplicity plan. Let us first decide which sized hive is the *better*. If the narrow hive is the better, then it is a serious mistake to make any more 10-frame hives. It might not seem so at first, perhaps; but, in *time*, the best will be used. I am aware that it is an advantage if a new thing can be used with an old one, and that the old one will not have to be thrown away; but in a progressive industry like bee-keeping, the old *must* give way to the new, *provided* the new is better. The old box hive *had* to give way to the movable-comb hive, and "'twas ever thus," the *best* will be used, and those who cling to poorer implements because they don't like to throw them away, are left in this race.

WIDE FRAMES AND SEPARATORS.

I should like to say a few words about your review of Mr. Heddon's book; but this article is already becoming quite lengthy. I feel that I must notice one thing, however, and that is the following: "It is a little amusing to see friend Heddon go back and declare in favor of wide frames, and *separators* also, after the way he has denounced them a year or two back. If I were he, I would be a little more mild in denouncing any thing, especially if I expected to change my plans within a year or less."

Can you show, friend Root, where he has harshly denounced wide frames or separators? I have spent half a day in "reading up" what Mr. H. has written upon the subject, going back not only "a year or two," but *four* years, and it seems to me that the remarks of yours are too severe. Away back in 1883, page 315, *A. B. J.*, he says: "Several correspondents have asked me if I considered it advisable to use separators with wide frames. I will reply, that I do. When I run 34 wide-frame supers, I tried omitting the separators. I find that, while the 'case' seems not to need separators to get reasonably straight combs, the wide frames are almost a total failure." In the fall of 1884, at the Northwestern Convention, see *A. B. J.*, page 679, "a vote was taken, and about three-fourths of the members could dispense with separators." Mr. Heddon said: "We have used a large number of one-story wide frames, in supers with separators, and a large number of cases in which no separators were used; and although there are advantages and disadvantages in separators, yet they have nothing to do with the amount of honey stored. Although only one-fourth of you now vote in favor of separators, *the time may come when you will vote the other way.*" (Italics mine.) "If you can produce honey without separators, so that it will suit yourself, your commission man, the consumer, and everybody, all right; if you can not, then use them."

Last May, in GLEANINGS, page 344, was an article entitled "Wide Frames and Separators." Mr. Heddon gives us all, upon this subject, that I have been able to find from his pen in GLEANINGS for the past four years. In that article they are certainly not denounced. Please allow me to quote: "I would rather abandon separators than use them in two-story supers. I do not think there is any system of using separators, equal to the wide frame, *when used one story high*. There are many advantages in the use of separators, and many in the non-use. I mean to continue the use of separators, and am now perfecting a different style of supers which I think will aid us greatly in their quick and easy manipulation, as well as their usefulness."

Please turn to the article, and read the whole of it. I can not find that Mr. Heddon has ever *denounced* separators; he has claimed, and still claims, that marketable combs *can* be secured without them; he has *always* admitted that there were advantages in their use, especially when used in connection with wide frames. He has always opposed wide frames *two tiers of sections high;* but he has freely admitted, that, when used one tier of sections high, wide frames have decided advantages, and has at times been at a loss to know which to use, the frames or his case. Before he had proved the advantages of reversing the sections, he had about decided in favor of the case. The advantages of reversing the sections turned the balance in favor of wide frames and separators. Is there any thing *amusing* about this?

I should also like to say something about "interposing two sticks and a ⅜-inch air-space" in the center of the brood-nest, but must wait until next time.

W. Z. HUTCHINSON.

Rogersville, Mich.

Friend H., I think from what you say, that perhaps I *was* a little severe on friend Heddon in regard to the separator business. I beg his pardon, and I thank you for correcting me. Perhaps it was wide frames to hold two tiers of sections that I had in mind. But I think you will agree to this: That when he adopted his new arrangement of a year ago or more, he decided to abandon separators; for it is almost out of the question to think of using separators with a case made in that way, and I believe the brethren generally understood that Heddon, by adopting that style of case, concluded that the advantage of separators was not sufficient to think of retaining them. Now, however, just as a good many of us are thinking of abandoning our old arrangements, and using the Heddon case so much talked about, he has dropped it and substituted a wide frame with separators. Of course, the wide frames hold only one tier of sections. I suggested that he had, very likely, good reasons for the change; but in view of making such changes, would it not be best for all of us to be a little slow in declaring or even deciding we have got the thing just right where it ought to be? These changes in implements, hives, and arrangements, are very demoralizing, and I don't blame a good many for saying, "I am not going to change any more until I can see some *very* good reason," and that this very good reason shall continue for at least a year or two.

COULD A COLONY OF BEES WINTER IN A GLASS BOTTLE?

A HINT IN REGARD TO MORE VENTILATION FROM THE ENTRANCE.

IN your comments on my article in GLEANINGS of Jan. 15, you ask the above question. Theoretically, if there is any truth in what I believe and act upon, a globular bottle made of thin glass, of a size only sufficient to contain a colony and its stores, the neck pointing downward, and about 2½ inches in diameter, with all except the opening protected by some non-conducting material, would be a perfect wintering hive. Of course, in practice we can not use hives of this shape, nor would I recommend glass as a good material to make hives of.

I do not mean to say that we could confine all the animal heat in such a hive, nor do I think that this can be done in any hive we can use, unless the outside air is of the same temperature as that on the inside. Two bodies of air of different temperatures can not be prevented from intermingling as long as there is a passage between. A good colony, packed as I would have them, will send a constant current of warm air out of the entrance. If openings are permitted in the top of the hive, the amount of heat thus lost will be vastly greater.

I wonder how many of those who claim that bees hibernate, or, in fact, of bee-keepers in general, know how much heat a colony of bees gives off. When the heat is allowed to pass through the top of the hive into the open air, there is no way of determining this waste. When a hive is closely sealed at the top, and well protected from the cold, almost all escape of heat is by means of the entrance. When this is covered with snow, something of an index is afforded as to the amount of waste heat by the melting of the snow. I am a firm believer in the letting-alone policy during winter, and consequently my hives are frequently covered with snow for a month or two. When covered in this way, the snow soon begins to melt away from the entrance, and I have often seen a wedge-shaped space thus melted, the width of the hive, five or six inches thick at the base, and almost as high as the hive. After this quantity is melted, the melting stops, as the snow gets so far away from the entrance that the outcoming air is cooled before reaching it. By careful estimation and experiment I have found that five pounds of snow are often melted by a colony in this way. I am sorry to say that I do not know just how long it takes them to do this. The present winter has not been a good one for finding this out. Speaking from memory, I should say that when the weather continues not much below the freezing-point, this amount may be melted in less than a month.

Now, to melt five pounds of snow requires 400 heat units (pound centigrade). This is an amount of heat sufficient to raise four pounds of water from the freezing to the boiling point, or enough to warm nearly ten and a half pounds of ice water to 100°, the natural temperature of the bee-hive. Remember, this is only the waste heat flowing out of the entrance during a period of certainly not more than a month and a half, and I think not over half that time.

It would be impossible to confine all the heat generated by a colony of bees by any method of outdoor wintering. The plan I have advocated comes nearer to it than any thing else.

Some might say, "Why not close or contract the entrance, and thus save more, or all of the heat?" The difficulty then would be to get rid of the moisture. We should have to run the risk of its ill effects, or employ upward ventilation, and thus waste more heat than by free downward ventilation.

Perhaps we may yet find out how to do it. I intend to keep on experimenting; but in the meantime my main dependence will be on small hives, large entrances, and enameled cloth above, well protected by chaff. 8—J. A. Green, 85—100.

Dayton, Ill., Jan. 21, 1886.

Friend G., you strike on a point that has often been in my mind, and has been a good deal talked about in years past, and I can not now see why it is that we have not made more of it than we have. It is this: Making the hive close and tight, all around, except the entrance, and leave that large enough to give all ventilation needed. The best colonies of bees I ever had were those that were strong enough to send a draft of warm air out of a good-sized entrance all winter long. You remember that this matter is touched upon in the A B C book; and while we are about it, I should like to see the experiment tried, of wintering a colony of bees in a large-mouthed glass bottle, say a two-gallon candy-jar. I believe with you, that it could be done, and I should not wonder if it would be one of the keys to success. The way to do it is to put some foundation in the candy-jar, and get the bees to build it full of comb, then fix it upside down, with three or four inches of chaff covering every part of the jar except the mouth. Leave the mouth open all winter, like a good many suspended box hives without any bottom. It is my impression, that the bees would take care of themselves, even if their stores were not extra. Who will try it?

MANY OR FEW COLONIES: WHICH?

FRIEND C. C. MILLER CONSIDERS THE MATTER PRETTY THOROUGHLY.

On page 22 Mr. Root asks me, "Would it not be better to take a little of the advice Doolittle gives in the present number, and get larger yields from fewer colonies, or else have them scattered more in different localities?" Now, Bro. Root, don't you know you ought not to rile me in that reckless manner? You needn't think, because I'm little, and you have Doolittle to help you, I'll stand *every* thing; so, here's at you both. As you ought to know, from my saying I hauled my bees away in the spring, I did not keep them in one apiary, but in two. That made about 90 colonies in each. Do you think a less number would have done any better? Moreover, my spring count, 179, was only 5 more than I had in 1882, when from 174 I took 16,549 lbs., to which you refer as an enormous yield. I have read Bro. Doolittle's article twice over. It is exceedingly interesting, and a valuable contribution toward the exploration of that region which, he very truly says, is "well deserving of our best thoughts and efforts." From the premises given, however, I do not make all the conclusions he and you seem to make. He says, "There seems to be a growing tendency of late to multiply our number of colonies, rather than see how good results can be obtained from a few." If this means, to possess a large number of colonies, without reference to the profit therefrom, the tendency is wrong: if it means, to multiply our number for the sake of multiplying our profits, rather than see what large yields per colony we can secure from a few, then the tendency is right. It has been too much the case that exceptional instances of large yields from a single colony have been quoted as patterns to be imitated; as, where A, with 50 colonies, gets 500 or 1000 lbs. of honey from a single colony. From his whole apiary he gets 4000 lbs., while B, with an equal number of colonies, gets 5000 lbs., getting from no colony more than 150 lbs. It is well enough to talk about A's big yield; but after all, I had rather imitate B's example. Of late years I have had some misgivings as to some of these large yields from single colonies. Not but that the owners mean to be perfectly truthful, but there are so many ways in which we may be mistaken. A few years ago I had a colony which gave me, if I remember rightly, 194 lbs. comb honey. If you had asked me, I should have asserted very positively that they had no help in any way, more than every other colony, and should, perhaps, been indignant if you had suggested there might be any mistake. I would not be so positive now. Without remembering it, I might have given them some partly finished sections, or, without my knowledge, another colony might have united with them.

There are many circumstances to be taken into consideration in deciding the proper number of colonies to be kept. Not only the resources of the field, but the experience, ability, tastes, and desires of the bee-keeper are to be considered. I believe I would place my own limit something like this: That number from which I can make the most clear money annually, due regard being had to my own enjoyment in the work. I once asked Bro. Doolittle why he did not keep a larger number of colonies, and I think he told me he did not want a greater number than he could care for without outside help. He probably is unwilling to take the extra profit he might have from a larger number, and pay for it in the price it would cost him in the worry the extra help would cause him. I respect his taste in the matter; and yet, another man seems to enjoy the bustle of a lot of hands under his direction, and his taste should be equally consulted. In one respect I am most fully in accord with you, and would like to emphasize the statement, that "the mania for rapid increase is oftentimes a very sad one." One thing bearing on this matter is not generally considered: Where bees are wintered in cellars, a score might be wintered in a given space, where one or two hundred would fare disastrously, and from no other reason, I think, than the greater number. Then the amount of pasturage must be considered; and here, Bro. Doolittle, is another important unexplored region. You refer, Bro. Root, to reports of beginners getting large yields from a few colonies, who afterward fail to get like results from large apiaries. Perhaps the work of beginners is apt to be more fully reported than those longer in the business; but, may not overstocking have something to do with the matter? I am not sure but my ground would be overstocked at some time of the year with any thing more than five or ten colonies. There are from five to eight weeks during apple-bloom and clover, when my bees have all they can do. During the rest of the time they are comparatively idle, although there may be no day when some bees do not bring in something; but the ground is overstocked for perhaps twenty weeks. It may be, that enough is gathered to keep busy five or ten colonies, and I imagine that, with this number, having six months to work in, I could make a pretty big report.

There is one point you make, Bro. Doolittle, that can not be disputed. If a given field yields, say, 45,000 lbs., and each colony uses for its own support 60 lbs. annually (I suppose they would use more than 60), then the fewer bees you can have to clean the field, the more honey you will have as surplus.

When it comes to having large numbers, additional help must be obtained, and comparatively few have the ability to superintend others successfully; so, because a man makes a grand success with just enough colonies so he can do all the work himself, it by no means follows that he would be successful with double the number, no matter how large the field nor how much help he might have. But I'm afraid I'm getting on the wrong side of the question, and must return to the charge on Mr. Root.

In 1881 I had the fewest colonies (67), and the largest average yield (117 lbs.) I have had in several years. In 1884 I had the most colonies (200), and the smallest average yield (54) in the same time. Now, which was better for me? It sounds better to say, 117 lbs. average than 54; but when 54 gave me a total crop of 2877 lbs. more than the 117, that settles it in favor of the many colonies and the small average yield. It is, however, quite possible that the best number lies somewhere between these two extremes, and that, with 175 colonies in 1884, I might have had a larger crop than with the 200. Certain it is, I do not care to have more than, if as many, as 100 colonies in one apiary. Now, Mr. Root, don't you see I don't need Bro. Doolittle's advice? and don't you wish you hadn't "riled" me?

TWO CHIPS.

On page 43 a statement passes unchallenged, that "moist air is heavier than dry air." Is this so?

My sub-earth ventilating pipe is 4-inch tile laid 3 or 4 ft. deep, and 100 ft. long. Much to my surprise, I have pretty strong proof that a longer pipe would not bring in air one degree warmer.

C. C. MILLER, 179—340.

Marengo, Ill., Jan. 21, 1886.

No, friend M., I don't wish I hadn't "riled" you, a bit; in fact, I would do it again right off now, if I knew just how to do it as well as I did the other time. I am very much obliged for the facts in regard to sub-earth ventilation, and I am surprised also; but I propose to use the information, not only for ventilating bee-cellars, but for making a greenhouse that will grow hardy plants and vegetables all winter long, with no artificial heat whatever. "Father Sun" and "Mother Earth" are to do all the heating, and you see if I don't get good results. Very likely I shall have to use shutters over the glass in extreme weather.—Now, in regard to this matter of many or few colonies, I believe, after all, you have considered the matter about as thoroughly as myself or Bro. Doolittle, and I think it will pay us all to read your article several times over. In our business of selling bees and queens, we make it pay to keep 400 or 500 colonies in one location a part of the year, although we have for several years back been reducing them to about 200 each fall; but as we buy something like 100 colonies from our neighbors each spring, no doubt it would pay us to winter over 300; so you see it makes a difference whether a man raises honey alone, or bees and queens as well as honey; and from our standpoint of view it seems to me it would be a pretty good thing for you, friend M., as well as honey-producers in general, to be prepared to sell bees, at least occasionally, when the season happens to favor the production of bees rather than the production of honey. See what our friend Oliver Foster did, even in selling bees by the pound, at a great deal less figure than the usual prices.

OLIVER FOSTER'S REPORT FOR 1885.

HOW HE SUCCEEDED, IN SPITE OF UNFAVORABLE WEATHER.

WE notice a marked variation in the reports of the honey crop in Iowa for the past year, which demonstrates that one year a few miles may separate good honey-producing localities from poor ones, whereas the next year these dividing lines may not exist, or the blessings may fall in other fields.

In this locality the past season has probably been the most unfavorable one of the ten in which I have been engaged in bee culture. In the fall of 1884 I packed in chaff, 280 colonies of Italians on their summer stands, in three apiaries. About 50 of these were three and four frame nuclei, and a large proportion of the others were made up of united nuclei.

After one of our severest Iowa winters, followed by a very cold late spring, the first of last May found me with 250 colonies in average condition, and with a fair prospect of selling them all before the honey harvest began, as per the editorial warning on page 601. I had bought 12,000 sections, and was planning to have them filled; but as many of the friends had lost bees heavily, and were anxious to have more, I decided to leave the sections in their boxes, run all three apiaries for increase, and let them *go*, and they *did* go, many of them before the increase came. By withholding advertisements all orders were filled promptly, except a few that included dollar queens before they could be furnished. We had no honey-yield worthy of mention, until white-clover bloom. The clover had winter-killed badly, except in sheltered places, and it yielded about one-fourth of a crop. Basswood did no better; many of the trees did not bloom at all. Had it not been for a fair yield from late bloom, many colonies would have been short of winter stores.

My account with the bees for the year foots up as follows:

To supplies, including circulars, postage, advertising, use of hives, buildings, machinery, horse and buggy, etc.	$236.00
To hired help	110.00
Total expenses	$346.00
By 16 colonies increase (full count)	$ 80.00
" 249 " sold (average $3.54 each)	881.40
" 60 queens by mail	59.60
" 1000 lbs. extracted honey (8 cts.)	80.00
" 300 " comb " (15 c.)	45.00
Total	$1146.00
	346.00
Net profit	$800.00

I now have 296 colonies in two apiaries, all packed on summer stands, and they could not be in nicer shape, apparently, at present writing.

I have been experimenting extensively on the wintering problem as well as on the different lines of summer manipulation, making improvements, as I think, each year, and I intend to publish my methods whenever they can be considered perfected, for it is demonstrated facts that we want, rather than theories. 10—OLIVER FOSTER, 250—296.

Mt. Vernon, Iowa, Jan. 13, 1886.

Why, friend Oliver, I had some way got it into my mind that you were a *small* bee-keeper, and here you are with 296 colonies, and doing nicely, even during a dull season. Best of all, you seem to be pleasing your customers right straight along; and, friend F., it does my heart good to have you speak of honey-yields as blessings from God. To be sure, they are blessings; and if more of us were in the habit of taking them that way, I shouldn't wonder if it would be safer for God to send more of them.

OUR OWN APIARY.

THE CONDITION OF AFFAIRS UP TO DATE.

ABOUT a week ago, during a warm spell, our bees were examined and were found to be in good condition. Yesterday Jan. 27, while strolling through the apiary I noticed that the entrance of one of the hives was spotted considerably, indicating dysentery within. The slate showed that this was an imported Holy-Land stock. At the beginning of the winter season I had noticed that these bees were very uneasy, and after a fall of snow they flew out even then. The snow, everywhere in the immediate vicinity of the hive, was spotted with little holes made by their chilled bodies. The apiarist says they acted like that last year, and that they barely pulled through the winter.

CLUSTERING OUT IN JANUARY.

Toward evening of the same day my attention was called to another hive where there was quite a bunch of bees hanging out at the entrance. Peering down into the hive after lifting one edge of the cushion up, we found that the bees were scattered through the interior of the hive, when seemingly they should have been quietly bunched up. Lifting one end of each frame separately, showed that there was scarcely 3 lbs. of honey, when, about two months ago, they had 25 lbs. of choice sealed honey. When put into winter quarters, inasmuch as it was a large swarm, it was supposed that they were in prime condition for wintering. Their restless condition, coupled with the fact that they had consumed such a large amount of stores, seemed to indicate that they did not then and had not enjoyed that quiescent state, or hibernation, as W. F. Clarke calls it.

BREEDING IN CHAFF HIVES IN JANUARY.

Jan. 28.—To-day the swarm mentioned in the above was overhauled to ascertain the trouble. It was a rousing big swarm when put up for winter, and the apiarist found that they had been breeding heavily. This accounts for their consuming so much honey; and when the weather warmed up they just crowded out at the entrance for more room.

POLLEN NECESSARY FOR BROOD-REARING.

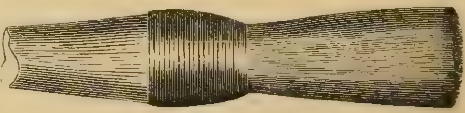
A careful examination of each comb showed that considerable pollen had been stored in the bottom of the cells, although the combs, when given them in the latter part of the fall, apparently contained nothing but choice honey. The presence of the pollen, together with the fact that it was a strong colony, well packed, undoubtedly induced the brood-rearing; and inasmuch as the honey was running short, the bees were probably compelled to consume more pollen than was consistent with healthful wintering. As a proof of this, the neighboring hives were considerably spotted. This would also account for their uneasiness. A report of these will be given later.

ERNEST R. ROOT.

BRUSHES FOR PAINTING BEE-HIVES.

ALSO SOMETHING ABOUT LOW-PRICED BRUSHES FOR OTHER PURPOSES.

TWO or three years ago we wrote to one of the largest brush-manufacturers in the East for prices of brushes suitable for bee-keepers. At the time, they declined to give us figures, but referred us to dealers in the large cities. I objected, and proposed to give them an order as large as the city jobbers; but as our institution was something not laid down in the books, they preferred not to sell to us direct. Of late, however, they have modified their views a little. I do not know whether it is because the Home of the Honey-Bees has grown bigger, or because the general depression in business has made manufacturers more anxious to open trade in almost any avenue. However, they sold me the brush I wanted. Providing I would take five gross at a single lot, they would let me have them so I can offer them to you at 10 cents each. Below is a picture of—



OUR TEN-CENT PAINT-BRUSH.

Perhaps I should not call this a paint-brush, but it does very good service for many kinds of painting. It is really a small-sized paint-brush or a large-sized sash-tool, and is very convenient for putting on mucilage, labeling honey-jars, moistening sections when they are too dry to fold otherwise, and many other like things. If wanted by mail, add 3 cts. each extra for postage. We can furnish larger-sized paint-brushes at correspondingly low prices. Our best one is worth 50 cts.; by mail, 8 cts. each extra.

WINTER TEMPERATURE OF BEES.

A REPLY TO G. M. DOOLITTLE'S ARTICLE, PAGE 190, MARCH 15, 1885.

MR. DOOLITTLE has laid his fellow bee-keepers under an obligation of gratitude by his thermometrical observations in regard to the degree of heat maintained inside a cluster of bees during the winter, as reported on page 190. Though his experiments have conducted him to a conclusion unfavorable to my views concerning hibernation, he has my thanks none the less; and I hope to show him, before I have done, that he has decided against hibernation on insufficient evidence. At any rate, I shall try to do so.

At the outset, however, let me say that the *American Apiculturist* is in error when it states, concerning entomologists, that "not one of this class can tell us any thing reliable about the winter temperature of the bee-hive." Huber, Reaumer, Newport, and others, have given us information, which, considering the sources of it, must surely be regarded as "reliable." Mr. Newport especially, made numerous experiments to ascertain the temperature of the interior of bee-hives in winter, which he recorded in a valuable paper published in the *Philosophical Transactions*, entitled "On the Temperature of Insects."

Huber tells us, as the result of his observations, that "the heat in a well-peopled hive continues 86 or 88 Fahrenheit, when it is several degrees below zero in the open air." He also says, that bees "then cluster together and keep themselves *in motion* in order to preserve their heat;" and that, "in the depth of winter, they do not cease to ventilate the hive by the singular process of agitating their wings before described." Mr. Newport was of the opinion that Huber was altogether in error in assigning a heat of 86 or 88 Fahrenheit to a populous hive, which, he contends, has its temperature sometimes (though rarely) lower than that of the freezing-point, and in the winter months does not average more than from 7 to 9 degrees above that of the atmosphere, or about 52, though merely tapping on the outside of the hive, by exciting the bees, will, at any time, greatly increase the heat: in one instance, Feb. 2, to 102°, when the temperature of an adjoining hive was only 48.5°; and it is from this circumstance that he supposes Huber's error to have arisen, as the mere excitement caused by introducing a thermometer is sufficient, to raise the heat to the point (86° or 88°) which that observer mentions. Mr. Newport admits that hive-bees are never strictly torpid, but *pass the winter in a state of hibernating sleep*, liable to constant interruption by considerable variations of external temperature or accidental excitement.

Mr. Doolittle's experiments prove the extreme difficulty, if not utter impossibility, of ascertaining the normal temperature of the interior of a bee-cluster; for the moment the bees are disturbed and excited, the heat begins to increase. It is natural to suppose that the bees at or near the outside of the cluster will be cooler than those at the center of it; yet they may be, and no doubt are, warmer than the air outside the cluster, owing to the transmission of heat from their companions who occupy an inside berth.

If Mr. Doolittle had noticed my article in the *American Bee Journal* of January 14, 1885, headed, "Chilled Bees are Not Hibernating," he would hardly have made the remark that I call "stiffened" bees "hibernating" bees. I there said, "Chilled bees are *not* hibernating bees, but bees undergoing the process of being frozen to death. In the early stages of this process they may be restored by warmth; but unless thus restored they will die. They are not on the road to death when they hibernate. This is nature's expedient for preserving them alive." I must ask Mr. Doolittle to read the whole article, from which the above is a brief extract.

My belief is, that bees, in a climate like ours, "pass the winter in a state of hibernating sleep," as Newport expresses it. Unable, before going into this state, to take food enough to last them any great length of time, they must necessarily rouse up at intervals to feed. I think they usually do this when spells of mild weather come. But, if the demands of hunger compel them to wake up and eat when the surrounding atmosphere is cold, they have recourse to that faculty of generating heat which Huber mentions, and with which all bee-keepers are familiar. During the present winter (1884-5) we have had scarcely any warm spells; but I have noticed that whenever we did have one there was a hum of activity in my supposed-to-be hibernating hives. This hum I have taken to be the sound of the dinner-gong.

"A well-peopled hive," as Huber calls it, is, no doubt, much warmer than the outer air, even when the bees have fallen into their hibernating sleep. How much I do not know, nor is it easy to find out, because the least disturbance of the bees raises the heat. But I am inclined to think there must be excitement before the temperature becomes 86 or 88°, as noted by Huber. I have observed the phenomenon of warmth under the cushion and just over the cluster of bees, mentioned in the editorial notes to Mr. Doolittle's letter, and so, doubtless, have most bee-keepers. We want to find out, if we can, what that degree of heat should be to enable bees to hibernate comfortably. Then we must try to ascertain the size of cluster, and dimensions of hive, necessary to secure that degree of heat.

I suppose if we could investigate a hibernating bear we should find the outer fur pretty cool; but the roots of the hair imbedded in the hide, would be warmer. Then if we could sink the bulb of a thermometer down to the region of the heart we should, no doubt, find blood-heat there. A cluster of bees, when balled and knotted up as tightly as possible, may perhaps be of the nature of one living entity, the outer bees in a state similar to that of the bear's fur, and the central ones warm as Bruin's heart, and, like that, diffusing heat and life to the whole cluster.

Mr. Doolittle thinks it "impossible for bees to hibernate when they must burn honey enough to warm a temperature of 16 below zero to 63 above." To which I reply: 1. When it is 16 below zero out of doors, it will not be so cold as that inside a chaff-packed hive with sawdust cushion on top, irrespective of heat generated by the bees. When it is 16 below zero in the open air, as it has often been this winter, I have found that it was not nearly so cold inside my wood-shed, which is only a single-boarded building. 2. It would not take much of a lamp to raise the temperature inside a hive, such as Mr. Doolittle experimented upon, to 63 above zero. Is it too much to believe that the respiration of 20,000 bees would suffice to do it? If it is, then we may add to this Huber's theory of motion inside the cluster to make up the deficiency. It is thought by some that there is a constant change of place between the central and outside bees, and this movement may suffice for the purpose. 3. The creation of this heat regulates the consumption of honey, but does not necessarily conflict with the theory of hibernation. Hibernation has its degrees. In the bear, it is profound and complete; with squirrels, it is partial. They rouse at intervals, and feed; so do bees. How often they wake, and what quantity of honey they consume during their waking spells, depends, I suppose, on the degree of cold they have to withstand.

The second paragraph of the editorial notes on Mr. Doolittle's letter states my idea of hibernation to a dot. The naturalist Reaumer describes in a similar manner what he calls "a sort of torpidity" which he regards as the normal condition of bees during the winter season. He says: "In winter, while it freezes, one may observe without fear the interior of hives that are not of glass; for we may lay them on their sides, and even turn them bottom upward, *without putting any bee into motion.*" He refers, of course, to old-fashioned box hives. He adds: "We see the bees crowded and closely pressed one against the other: little space then suffices for them." This harmonizes exactly with friend Root's account of his "ball of bees about the size of a large apple," which unlocked itself and expanded so that "they filled the hive pretty tolerably." I say with friend Root, "I should like to have my bees winter in these tight little balls; at least, it seems to me that is what we want." This is what I intend by hibernation; and I maintain, that when we find out how to bring this about every time, we shall have mastered the winter problem.

Speedside, Ont., March 23, 1885. WM. F. CLARKE.

A KIND LETTER FROM CALIFORNIA.

QUEENS TAKING THEIR WEDDING FLIGHT WHEN ONLY 24 HOURS OLD.

IN my little mountain home, many miles away from church privileges, with only towering mountains, rushing waterfalls, and Lytle Creek roaring in its rocky bed, to remind us of Him who made them, your Home talks come to renew and strengthen all that is noble and right.

The year that has passed has been the fallow year to the California bee-keepers. I did not take out a pound of honey; but the bees are in good condition, with ample natural stores. There was no rain from Dec. 21st, 1884, until March 7th, 1885, and but little after that, so there was a dearth of bee pasturage. In March, bees did fairly; plenty of brood. Then came cold weather, which stopped the honey-flow, and lack of moisture did the rest.

I had two natural swarms. I raised some queens for home use. One lot of cells was so large that I watched them closely; on the 14th of June, about 10 A. M., I saw the first emerge. I had given the cell to a queenless colony. The young queen was black, and very large. The next day, about 2 P. M. I saw her on the top of the hive, just returned from her wedding flight, with a filament attached to her abdomen. I took her carefully in my hand, and examined her, lifted the cover, and put her on top of a frame, where the bees began to caress her, and in two days I found plenty of eggs. I was very much delighted, for I never expected to see a queen returning from her wedding flight. I find her bees are hybrids, and very industrious.

THE SUN EXTRACTOR, AGAIN.

The sun extractor for rendering wax is in common use here. I have used it for that purpose four years. It is made like the one described in GLEANINGS. If one sash will not gather the sun's rays so as to have sufficient heat, put another over the first, and that will be *sure* to work.

THE MOTH WORM IN CALIFORNIA.

As Mr. Israel says, people at the east know nothing about the bee moth. It takes hot dry climates to show what they can do. They have never troubled my swarms much, as I watch them; but if one tries to save combs, then comes trouble. In less than a week, five frames had seemingly a thousand cocoons. The space between the frames was packed solid, and I had sulphured them too.

MRS. W. W. WILSON.

San Bernardino, Cal., Jan. 2, 1886.

Thanks for kind words for the Home Papers, my good friend.—Your fact, to the effect that a queen may take her wedding flight the day after she is hatched, seems pretty direct; but still there is a possibility for a mistake. Your queen may not have left the hive at all, and another one resembling her may have alighted on the hive. Under such circumstances she would probably be well received, and commence laying as you suggest. As others, however, have reported that queens do sometimes take their flight when one day old, it may be so, though it is very rare. In such cases we should suppose the queen was very fully matured before emerging from the cell. Your California climate may have something to do with it.—In regard to the solar extractors, I can not yet feel quite satisfied that two thicknesses of glass will give more heat than one. Have the friends tried both ways, enough to be sure that the second sash is an advantage?—Very likely the moth are worse in California because you have no zero freezes to kill them out of combs not protected by the bees.

BEE-KEEPING IN KANSAS.

SOME REASONS WHY THE BUSINESS CAN BE CONDUCTED SUCCESSFULLY IN THIS STATE.

THE season of 1885 was a very poor one, being too wet until August, which, as usual, was a little dry. Spanish needles began to bloom Sept. 1, when a heavy rain fell, which destroyed all the early blossoms. From the later bloom, which lasted about ten days, the bees filled their hives (which were destitute of stores), and I took from four colonies 110 lbs. of nice section honey in 1-lb. boxes.

I began with 8 colonies — 7 strong and one weak. I increased to 14, all in good condition for winter. I think I have learned a valuable lesson this season, which is this. If I had fed my bees early in the season, to stimulate, I should have had 100 lbs. more honey to have sold. I sold my honey at 20 cts. per box, at our little town of Edna. I shall try a little extracted honey next season. The people here think that extracted honey isn't pure; but I believe I can persuade them to use it in preference to comb honey, by getting a few copies of T. G. Newman's "Honey as a Food and Medicine," which I can hand to my retailer to give to his customers.

In regard to the honey-producing plants of this section of Kansas, I will say we have no bloom after apple (excepting a few prairie flowers) until the first of Sept., when the Spanish needle and goldenrod bloom. For the last year only has white clover been sown, and then only in door-yards. I'm trying to persuade the farmers to sow the seed in their pastures, as it catches very quickly on the prairie sod. Basswood grows finely here. Two of my neighbors have several small trees growing, which look nicely for the time they have been planted—2 years. I intend to plant a few hundred as soon as convenient.

I think this will be a fine country for bees when we get plenty of white clover and other small honey-producing plants growing. One great advantage in bee culture here is the winters being mild, although we have some severe cold spells which last but few days—never so long as to prevent bees from flying during any month in the winter. As to chaff hives, I think they are of little use here, as the Simplicity, with division-board and good chaff cushions, affords ample protection. I have been handling bees for four winters here in this State, using only the duck quilt as protection, and I have never lost a colony. But I think bees might be more profitably wintered by the use of chaff cushions.

This fall I prepared my bees for winter as follows: 8 colonies have 6 frames each; 4 have 5, and 2 the full 10, all of which are well filled with sealed honey. I use the L. frame and Scovill Simplicity hive. Those frames containing the most pollen I stored away for spring feeding. My bees are all right up to date; but at present we are having very severe weather—the coldest since I have been in the State.

Now, friend R., I want to thank you for your ably edited journal; also the many able contributors for the valuable information imparted.

6—W. E. POTTS, 8—14.

Edna, Kansas, Jan. 11, 1886.

FLORIDA.

THE ADVANTAGES AND DISADVANTAGES CAREFULLY CONSIDERED; SOMETHING FOR THOSE CONTEMPLATING GOING THERE.

HAVING received quite a number of letters, which still continue to come from persons in the Northern States, inquiring about bees in Florida, the price of land, health, and other things pertaining to Florida, I shall attempt to answer such questions as would likely interest many of the readers of GLEANINGS. In the first place, I had better state that I have been here only one year and one month. Nearly every letter contains the question, "Can I make a living keeping bees?"

In this locality—high pine land, with a considerable number of orange-groves bearing, together with what palmetto there is, an expert might keep himself and small family from the sale of honey alone; but I would not or could not advise any one with a family to pull up stakes and settle in a high pine region, relying on honey alone from his bees to keep him. The orange does not yield honey profusely, but it blooms long—longer than white clover, I believe. The saw-palmetto did not yield much honey last season; besides, it can not be found growing abundantly on all high pine land. It grows on flat and low land. With my present number of colonies of bees I hope to be able to give an interesting report next spring in regard to the above-named honey-plants in this locality. I should think the hammocks and low lands along rivers would be much better for bees than high pine, although such places probably would be deprived of the honey-yield of the orange. But people settling on these kinds of lands, if I am not mistaken, are liable to have malaria. If you want to get as far as possible from malaria in Florida, you must reside on high pine land; then, if you have never had it before coming here, you are not likely to get it. I draw this from my own experience, observation, and conversation.

Another class of land for the bee-keeper is the coast region—Atlantic and southern Gulf coast. I understand these latter places are *excellent* for bees; but about getting the honey into market at a good price, I have not had any information. Nice comb honey, in 1-lb sections, retails at twenty-five cents in Orlando, but extracted honey from the coast sells very slowly at forty cents per quart, or about 12½ cts. per lb. Now, to sum up the location for bees, oranges, and health, I do not think it possible to get one single location *excellent* for all three.

As far as I know, it would be cheaper to bring bees along, if possible to do so, than to buy here; for people having bees do not want to sell them until after the spring honey harvest; yet a few can be bought at eight to ten dollars per colony. If native bees in box hives can be found for sale they usually sell at about three to four dollars per colony. At present I do not know of any.

I was told before coming here that a swarm issuing any month of the year could gather enough honey to keep it. This, I am quite certain, is a mistake, and should be corrected. I am confident that a swarm hived on fdn. the first of this month would have starved to death, for it has been too cold for bees to fly much, and the last recent freeze stopped brood-rearing in all my colonies. Last January was too cold for bees to gather honey, except a *very few days*. Had I hived a swarm on fdn. last July or August, I believe it would have perished before the fall flowers bloomed. I think it is important to know about this, as it shows the honey resources of the locality. Bees will gather enough honey in October to winter on, and rear brood ready for the spring honey-flow.

Five acres of land is all anybody needs to grow oranges and keep bees, and it sells at all prices—from $1.25 to $500 per acre—owing to the prospects of the town. In three miles of Orlando, which is considered the most prosperous place in South Florida, it sells at about $100 or more per acre for first-class orange land. Further away, $60 to $100. Second-class orange land brings about $25.00 to $50.00 less than above. In new settlements, with fair prospects for railroad, good orange land can be purchased at $10.00 to $25.00 per acre. Hammock lands are the best for vegetables; but oranges also are grown on some of these lands with less fertilizer.

Another question from correspondents is, "If I can not get a living keeping bees, what can I do till oranges bring an income?" For various reasons this question is puzzling to answer, because our

Creator, in his wisdom, arranged it so the most natural way to procure a living is to till the soil, and our Florida soil is quite poor. Although a few seem to get some profit out of gardening, yet I think it would be a vexation of spirit to the average farmer, unless on hammock land. Sweet potatoes do well; the squash family grows well; cabbage does fair to well. Everybody does not farm, even in a farming country; and, bear in mind, it is as easy, if not easier, to get a living here, aside from tilling the soil, as in any country. If you have a little loose money —or, rather, considerable—buy town lots, build dwellings, and rent them. Every house in Orlando is rented at a big rent as soon as built. I presume it is unnecessary to say, if a person has no capital, and is unable to work, he should not come to Florida, for the "bread fruit" does not flourish here. The cost of living is some higher than in Ohio, but not so much higher as one might think. I think all the canned goods sell as cheap here as in Ohio. Experience has taught me this: If you are an invalid, and are coming here, bring your woolens and flannels with you. And now let me say, in conclusion, that I have tried to give the plain naked facts; that I have taken more pains, I believe, to show the "*stuff*" of the framework than the veneering with which it is covered; that I have had a cramped feeling, for fear I should occupy too much space in GLEANINGS, but I must utter this: That keeping bees and growing oranges in connection, to me is most fascinating; and he who kneels to the living God may deny himself of many of the comforts and luxuries of life, and still be happy following these two pursuits in this glorious climate of Florida.

Orlando, Fla. L. W. GRAY.

FROM 56 TO 125, AND 8500 POUNDS OF HONEY.

94 LBS. OF HONEY FROM ONE SWARM IN ONE WEEK.

I HAVE had considerable experience in bee culture for the last fifteen years or over. I had bees in the Langstroth hive in the summer of 1869. I then resided at Pendleton, in the county of Prescott, Ont., an excellent locality for bees. That year I collected 1000 lbs. of honey from four two-story hives. This was before I ever saw a bee-journal, or heard of such a thing. I have had some ups and downs since I commenced; still, I have been able to hold my own well, up to the present time. I give your publications the credit of the greater portion of my success. I have shared at times somewhat in Blasted Hopes, but generally caused somewhat by my own neglect.

The season of 1885 I commenced with 56 hives, 10 of which were very poor. I increased to 125, and collected over 8000 lbs. of extracted honey. I have used and wintered bees on frames of nearly all kinds between the L. and the Jones two story and single-story, and the size I like best is a frame 10½×14 inside measure, 8 frames with two-story, gotten up similar to the Simplicity hive. This is a cold climate, and I have been induced to believe that a deeper frame than the L. is a more suitable one for our cold long winters. I do not pretend to give a 16 years' experience in bee-keeping in this letter.

There is one more fact which I wish to add to the report of last season. During the second week of July I obtained from one first swarm, put in empty combs, 94 lbs. of beautiful thick honey. The swarm was hived on Saturday at noon, and the following Saturday noon I removed all the combs from the hive. The queen had deposited eggs in two combs only. This was the third time I extracted during the week. Said first swarm came from a box hive which remained clustered for a long time, as box hives often do, until the box was almost covered with bees.

DON'T EXTRACT TOO CLOSE—A SUGGESTION.

The bees were well rested during their stay in the old hive. This gives me the idea that bees can make up for lost time. I don't believe that it pays to work bees right up to the end of the honey season. If hives are closed in giving them only the number of combs required to winter on quite early in the honey season—that is, after the swarming fever is over—the bee-keeper suffers no loss. For instance, about the middle of July last, after I obtained 8500 lbs. of honey from my 125 hives, I felt sure I should have no more swarms, so I took all combs from each hive, except those intended for the bees to winter on. I then prepared them for winter by closing them up with division-boards, top frames off, covers on tight, and sawdust behind division-board. At this date each hive had a good queen. The question is, Have I lost? did my bees gather honey-dew? I don't think bees will under such treatment. But if I had extracted up to the last of August, all that I could take from them, and left them almost in a state of starvation for a month or so before feeding up for winter, I should expect nothing surer than that my bees would become demoralized.

I have never practiced feeding very much, except when a scarcity of honey comes in mid-summer, or immediately after frost kills the flowers in the fall, which is generally before the middle of September. Then I feed all stock that require winter stores, until they have sufficient. I feed as fast as they will take it up, and then stop. I don't believe that feeding to stimulate breeding after the flowers cease to yield honey and pollen, pays. Bees will not always breed at this season; and if they do, I think bees raised under such circumstances are much inferior to those raised under the natural impulses. Queens bred late in the fall are worthless; worker-bees raised late in the fall are equally worthless — at least, from my experience I think so.

JAMES MOFFATT.

Maxville, Ont., Can., Dec. 25, 1885.

PERFORATED ZINC FOR THE PREVENTION OF ABSCONDING SWARMS.

A GOOD REPORT FOR THE ALLEY DRONE AND QUEEN TRAP.

I WANT to tell you of a little experience that I have had with Alley's combined drone and queen trap, and see if you will not agree with me that, in point of convenience and labor saving it should be ranked along with the honey and wax extractors and smokers. On the 14th day of March, 1884, my son and only child came home from college, sick. His disease was typho-malarial fever, which lasted him 72 days, during which time my bees increased from 20 to 48 colonies by natural swarming. Had it not been for two of the above-named traps that I had, it would have been impossible for me to have secured half the swarms, and at the same time nursed and taken care of my sick child. As it was, when a swarm would begin to come out I would run and put a trap at the entrance, and by the time I could get my empty hive in place with a few frames of brood from the parent stock in it, and the foundation all right, the bees would miss their queen and come back pellmell in search of her, and thus enter the new hive at once. In about 20 minutes the bees were hived, and went to work at once without further trouble or ado, and I was back in the house with my sick boy. In hiving them thus I moved the old hive to a new location, and put the new one in its place, and let the queen run in with the bees. It was a beautiful sight to me, to see my golden Italians come pouring in a stream, so to speak, from the top of a tall elm-tree into their new hive, without any climbing of trees or sawing off limbs, thus saving disfiguring the symmetry and beauty of a favorite shade-tree. I had no help, except a neighbor's little boy. After doing the chores at home he would come over and stay a few hours in the middle of the day to watch my bees, and tell me when they were swarming. I do most truly and heartily thank Mr. Alley for his invention, and I would about as soon think of going back to the old gum hive as doing without the combined drone and queen trap. We are having a very mild winter so far here in Texas. It has not been cold enough to form ice worth speaking of but once, and it all melted long before night. We had a nice rain this evening, with a little hail. MRS. S. E. SHERMAN.

Salado, Texas, Jan. 1, 1886.

Mrs. S., I am very glad indeed to get this report from friend Alley's drone-trap. I know friend A. has spent a great amount of time and money in experimenting, with the end in view of getting a device that will do just what you say his has done. I suppose, too, you will excuse me for suggesting that it was not an expert, either, or am I making a mistake? At any rate, my good friend, you made the device work nicely, and surely our veteran bee-folks ought to be able to do as well.

EGG-LAYING OF QUEENS.

SOMETHING FURTHER ON THE SUBJECT, BY OUR GOOD FRIEND CHARLES DADANT.

IN GLEANINGS for Jan. 1st, Prof. Cook writes that the queens know what the sex of their eggs is before laying, and that the dimension of the cells has no influence on the sex, which depends on the arbitrary will of the queen. He admits that some young queens lay drones in worker-cells, but he thinks that it is because they do not know yet how to manage the delicate apparatus of the spermatheca. To support his theory, he adds that Sir John Lubbock has noticed that the female wasps are provided with a wider knowledge, even, than the bees; for not only do they know the sex of their offspring, but they take care, also, to prepare a greater number of spiders in the cells destined to receive female eggs, than for male eggs, since the female wasps are larger than the males.

For at least twenty years I have practiced the replacing of drone comb by worker comb in the brood-chamber. It is an easy matter now, since we have the foundation; but before this invention I used to buy all the comb of dead colonies, at my neighbors'. The result was, that my colonies raised very few drones. Occasionally, and very exceptionally, a queen was found laying some drones in small cells; but certainly more than nineteen queens out of twenty did lay but very few drones in some occasional drone-cells; yet these queens did not seem dissatisfied with my depriving them of their option of laying drone-eggs. We have had a number of queens which did not lay 300 drone-eggs in their whole life; therefore it seems to me that a queen, in good health, lays drone-eggs in drone-cells because they are greater; and worker-eggs in worker-cells, because they are smaller; and that, if my queens had had the volition of laying drones, they would have laid drone-eggs in worker-cells, as some did at times.

That the dimension of the cell has some influence on the sex of eggs is so generally admitted, that Mr. Cook himself, in his scientific bee-book, recommends, with all the bee-writers, to replace the drone comb in the brood-chamber with worker comb, "not to get myriads of those useless gormands."

If the queens, while laying, were moved by the desire to lay drones, as most writers pretend, our replacing of drone comb by worker-cells would be useless. As for the young queens, I have often noticed that, in the first weeks, some lay more or less drone-eggs in worker-cells; but I have, every time, noticed that these young queens were of small size, and that this irregularity disappeared as soon as they were fully developed. Therefore it was the size of these young queens, which, being too small for the size or the depth of the cells, had compelled them to lay drone-eggs. The worker-cells had acted on these small queens as the drone-cells do toward large queens. Then in this case also the sex was determined by the dimension of the cells, and not by the volition of the queens.

But there was a point which seemed to overthrow all these inferences. The combs of the wasps have all their cells of about the same dimensions; yet the mother-wasps raise males and females; then the dimension of the cells has no influence on wasps, and the difference of the sexes may be the result of the volition of the females. Such remarks, which came several times to my mind, were a cloud on the above theory, and Mr. Cook has just dispelled it.

The cells where the male wasps are raised are not provided with as many spiders, hence they are *not so full* as the cells where the females are raised. Are Messrs. Cook and Lubbock quite certain that such difference in the fullness of the cells, or in the length of the vacant space in the cells, is not the cause of the difference in the sex?

When the eggs of animals are mature they don't wait, but drop. Suppose that, when a mother-wasp prepares a cell to receive her egg, the weather ceases to be propitious for her hunt, or that the spiders are not easily found; the cell is provided with only half the spiders needed, yet the egg can not wait, and has to be laid on these scant provisions. Why not admit that such a condition of the laying does not afford impregnation, and that the result is a male wasp? Who could say that this theory is not as rational as the one which endows the mother-wasp with the knowledge of her future offspring, and of its comparatively smaller or greater needs? To sum up: As we can control the laying of our queen by replacing the drone combs with worker combs; as the young queens lay drone-eggs in worker-cells as long as they are undersized; as the conditions of the cells in which the female wasps lay are different, and according to the sex produced; as no proof exists that any animal knows and determines in advance the sex of its offspring, I think that it is rational to conclude that the external conditions which are present at the laying of the queen have a positive influence on the sex produced. I should gladly see some discussion raised on this interesting topic. **CHAS. DADANT.**

Hamilton, Ill., Jan., 1886.

Friend Dadant, you really surprise me by the depth of reasoning you have given this very wonderful subject. You suggest many things that I hadn't thought of; and although I am left more in a maze than ever before, I think you have opened up a great field for investigation in a way it has never been opened before, to my knowledge. I know that removing drone comb is a great factor in preventing the production of useless drones; but it didn't occur to me before that this was a powerful argument in favor of the old Wagner theory — that the size of the cell might determine the sex of the offspring. I should be very glad to hear from Prof. Cook again after he has considered the facts you place before us.

VARIOUS MATTERS.

HOW MUCH PAIN IS THERE IN THE STING OF AN INSECT?

ON page 856 of GLEANINGS for Dec. 15, 1885, I see friend Root wishes to know more about the testing of the water in that well which gave an average temperature of 42°. I will tell you all I know about it. The man owning it is one of the oldest bee-keepers in our town; and as it is natural for the younger bee-keepers to visit the older ones, it so happened that I used to go often to see this man to talk bees, twelve to sixteen years ago. Being thirsty one hot day in July while there, I asked for a drink, and he went to the well and drew the "old oaken bucket" full of water, and handed me a glass of it. As I began to drink I stopped and spoke of its coldness, for it seemed to me equal in coldness to any ice water I had ever drank. He then spoke of the facts I gave on page 856; and to prove the matter to me he took a thermometer off a nail close by, which was showing some 90° in the shade, and placed it in the bucket of water, lowering the same into the well.

"Now," says he, "we will go in the bee-yard for a few minutes while the exact temperature is being registered in the well," which we did; and when we came back the thermometer showed between 42° and 43°. It was just such a thermometer as you sell on your 20-cent counter, and I supposed it was accurate. If I can think of it I will take my spirit thermometer along the next time I go that way, and make a further test of it.

HOW LONG A BEE LIVES AFTER STINGING.

By what I see in GLEANINGS I find an effort is being made to find out how long a bee lives after having left its sting; but so far I think the reports only point toward confinement being the cause of the death of the bee, rather than the loss of the sting. If a single bee is confined alone it will rarely live a great while; but if a dozen or two are put together with their queen they will live for a much longer time, but not so long as if they had their liberty. Now, I wish all the little folks (or big ones either) who try the experiment to see how long a bee lives after stinging, to put such a bee in with a dozen or two other bees which have a queen, and then tell us the result. While they are thus experimenting I will tell you what I know regarding the matter.

A year ago last August, while preparing a queen for shipment, one of the workers stung my fingers in getting it in the mailing-cage, which is a thing that happens occasionally with me; but always before this, and since, I have gotten them out of the cage, or secured them before they were in. But this bee was so spry that I could not get hold of it, and so I concluded to let it remain. This was at about 10 o'clock A. M. The caged queen and bees were left on my shop-bench all that afternoon, and till the next morning at 6 A. M. (or 20 hours), when the cage was wrapped and gotten ready for the seven-o'clock mail. At this time every bee in the cage was alive and smart, the one that left its sting in my finger being as lively as ever, as I could easily find it by the thread-like attachment which still hung to it. About this time I saw an account in the *Bee-Keepers' Magazine*, by J. Hasbrouck, if I mistake not the paper and the writer, telling of how a Syrian bee stung him, after which it was so persistent in trying to sting again that he caught it and put it in a cage with some other bees which he chanced to have caged. This bee he said lived a week when he let it have its liberty again. I may have made a mistake in some of the minor details, as I quote from memory. If Mr. Hasbrouck's eye meets this, will he not tell us all about it?

SMOKING BUMBLE-BEES AND HORNETS.

On page 636, R. Robinson speaks of "jugging" bumble-bees, and says that smoke "would do no good" in quieting them. The reason must have been that friend R. did not smoke them in their nest. Smoke does little or no good on cross honey-bees when they get in the air, and the same can be said of any kind of bees, hornets, or wasps; but take them in their nests, and a little smoke quiets them as effectually as need be; at least, such has been my experience with both bumble-bees and hornets. I have removed several objectionable bumble-bees' nests from about my premises by the use of smoke during the past ten years, and at one time I had quite an experience with a hornets' nest. This was about ten years ago, when I still managed the farm. One day I wished to sort some sheep, so I yarded them under a shed which I knew contained a large yellow-jackets' nest behind one of the braces. As I went in among the sheep I noticed the hornets thick about the nest, but thought they would not molest me; but as I reached out my hand to take hold of a sheep, one of them struck me, stinging at the same time, and, oh how it *did* hurt! I had got used to the sting of the bees, so it hurt me but very little; but this foreign poison affected me so I nearly fainted away, and I nearly lost the use of that hand and arm for four or five days, it was so swollen and inflamed. Well, I went to the shop, got the smoker, and after putting on veil and gloves I went cautiously to the nest, and before one was aware of aught save safety, I was pouring the smoke into the nest in a thick volume. The result was, that they began in a few moments to leave the nest, and, after hovering around for a few moments, they left, and I never saw one about the nest afterward. I should judge there was nearly a pint of them, as it was a very large nest.

Borodino, N. Y. G. M. DOOLITTLE.

Friend D., I have all along had a notion in my head that I had seen bees in the hive with this thread-like appendage, indicating that they had lost their sting; and I shouldn't have been surprised had it been decided that they would live as long without a sting as with one. Perhaps the juveniles will need assistance from their fathers and mothers in making tests, by placing the stingless bee in a cage with some other bees. While shipping queens we can easily put in a bee or two destitute of stings, and then ask the recipient to report.—Your experience with hornet-stings is much like mine. One day I dropped a coal out of the smoker on my hand. Supposing, at first, it was a bee-sting I let it lie until I could conveniently remove it; but I mentally decided that the bee was stinging rather milder than usual. When I saw that it was a coal of fire that had burned a blister, I mentally noted down that I had, by accident, positive proof that the pain of a bee-sting is much more acute than the pain of leaving a burning coal on the bare flesh. But we are so used to bearing bee-stings with a martyr-like spirit that we hardly recognize how much fortitude it does require. While I am about it, it is my impression that there is more pain in a bee-sting than in having our flesh burned with fire, or cut with a surgeon's knife. By force of habit we shudder at the knife or fire, while we have learned to take the bee-sting as a matter of course. Well, I got stung by a yellow-jacket; and as I had been taking bee-stings as a matter of course, I perhaps took the yellow-jacket in the same way. But I was considerably surprised to find that it was a different kind of medicine, having a good deal more "pungency," as nearly as I can express it. I was prepared for the familiar sensation of a bee-sting, but not for the different sensation of a yellow-jacket, and therefore I made as much fuss about it as I used to when a boy in the huckleberry swamps.

HONEY IN PLACE OF SUGAR FOR MAKING CORN BREAD, ETC.

MRS. HARRISON OFFERS A RESOLUTION.

FRIEND ROOT:—While I was getting dinner I had a revelation; and with your permission I'll tell the women about it—the *men* needn't listen.

I was stirring up corn-bread, lick-at-a-cut, and I thought I'd put in a spoonful of sugar, to make it a little sweeter and richer, you know, when my eye rested on a bowlful of honey. The other fellow within said, "Why not put in a spoonful of honey?" Yes, why not? Mr. Muth produced evidence at the late convention at Detroit, proving that honey is sweeter than sugar and syrup, and why not use it? Worth more than sugar? Suppose it is; it takes time to sell honey and buy sugar, and why not use it and save tariff?

The new year is a general time of paying off old scores and making good resolutions, and I put this motion before the house:

Resolved, That we (honey-producers) boycott sugar and syrup of all kinds, as far as practicable, using, in their stead, honey, the purest of sweets, believing that this course, and this alone, will bring forth good to ourselves, and the land in which we dwell.

"What is sweeter than honey?" is an open question since the time of Samson, and is as yet unanswered. Bees lived upon it for thousands and thousands of years, and no complaints are recorded of its not being good enough, until the last decade. Now it is advocated to take away the honey from the bees, and give them sugar syrup instead, benefiting the sugar market to the detriment of honey. Are we going to teach the bees that their own production is not fit food for them, thereby imitating the wealthy manufacturers of oleomargarine, butterine, and glucose? No: if they can't live on their own production, let 'em die. Are we going to extract their honey, and go to the great labor of feeding back to them in return sugar syrup, and let the honey go begging for a market at four and five cents per pound? Not much, if the court knows herself."

Now let us feed our bees the dark, rich, good sweet honey, and not depress the market with it. What the bees can not consume, use in pickling meats, preserving fruits, making vinegar and ginger-snaps. Put it into the mince pies, doughnuts, bean-pot, where beans are baking, in lieu of molasses, and make it into taffy for the children.

Dr. Mason, of Ohio, had square blocks of candied honey at Detroit, that were far superior to any confectionery that I ever tasted. He gave me some, and I ate and ate, and I could not find a place to stop; and if I had not been taught manners when I was a child, I'd been eating yet. If I drank tea and coffee (but I don't, our water is so good) I'd sweeten some with it, and see if it would be bad to take.

It is a mistaken idea, that honey was given to us to ship by carloads to large cities. Stuck-up city folks don't even know it is there—don't see it; they telephone to their grocer for silver drips, honey-dew, and pure maple syrup from the woods of Vermont, while Chicago has a larger sugar camp than all New England.

Now let's have less of this foolishness; eat all we can, pay every debt we owe with it, make it legal tender; sweeten all our pet charities; the Christian home mission; foundlings' home, orphans' home, old-ladies' home, and, by all means, don't forget the shoe-blacks; see that your minister's table is well supplied; and if your doctor doesn't eat honey, don't take his pills any more. In England, sugar is so cheap they have been experimenting to see if it would not be economical food for stock; and isn't it worth our while to see if honey wouldn't be excellent food for the old cow? MRS. L. HARRISON.

Peoria, Ill.

Mrs. H., I second your motion; and if I were president I would ask all in favor to please say aye. As the price of honey now is getting so near the price of sugar, all that is needful is to decide that sealed honey is as wholesome as stores of pure sugar. Below we submit a paper from another friend who has got the same ideas in his head you have. He is a little more vehement about it than you are, it is true.—In regard to blocks of candied honey, if you were taking GLEANINGS so long ago you may remember that was once a big hobby of mine; but I got over it for the simple reason that nobody seemed to care very much about it. There is another thing, too, you may not discover. Blue Eyes and her mother found out that these blocks of candied honey when melted made the nicest kind of confectionery. By all means, let us try to introduce honey everywhere, even to our domestic animals, as you suggest. Horses are fond of sweets, and a great many times it seems to encourage them to give them a lick of sugar. Now, wouldn't a lick of honey help them to take an interest in our plans and our work in the same way?

SUGAR SYRUP FOR WINTER STORES.

IS IT ADVISABLE, ALL THINGS CONSIDERED?

FRIEND ROOT, do you know that we are building up the sugar-trade at the expense of the honey-producers of this country? The universal law is, to provide first for our own house, and then, if we have any thing to give, we can help the sugar-men. We blame the newspaper men for saying that we feed the bees sugar syrup, and then sell it for honey. I for one don't see how they can very well help saying what they do, as long as all of the bee-journals and leading bee-men advocate the feeding of sugar syrup. I wish I could tell how many times in the last year you have said, in your foot-notes, "Feed sugar syrup." It is very embarrassing to me when I go to the city to sell honey, and begin to show my samples, to have the merchant look up, with significant grin, and ask me what I fed my bees. I have 1400 lbs. of nice white comb honey that I have been unable to sell. Our home market is glutted with honey; and the worst of it is, that it was sold for less than the best grades of sugar bring. I for one have fed the last pound of sugar, unless necessity compels me to. If my bees run short next spring I shall feed section honey before I buy sugar. My experience is, that bees fed well-ripened honey will winter just as well as those fed on sugar. Bees fed on honey last fall (1884) wintered much better than those not fed. I have fed some colonies this fall on a poor quality of last year's honey, and we shall see how they tally in the spring.

Friend Root, you remember that a few years ago you rode the grape-sugar hobby until your hobby was besieged and demolished by solid facts; and the sooner your granulated-sugar hobby suffers the same fate, the better it will be for the bee-keepers of the country. If the hundreds of thousands of pounds of sugar fed to the bees were left where it belongs, and the bees were fed on honey, the market would not be glutted, and we should get a fair price for our honey, and there would be a call for it. A man not far from here fed sugar syrup this fall to get partly filled sections filled out, and then sold it for honey. It isn't all gold that glitters. Some bee-keepers have got it in 'em bigger than a woodchuck. Unless there is a change in the administration in bee affairs, I am going to go it on back numbers, and let GLEANINGS live on carp.

You remember how you mourned over the wreck of your grape-sugar hobby, and there is one thing certain—that sugar feeding or bee-keeping has got to go down. Are you aware that the best grades of extracted honey don't net the producer as much as we have to pay for the poorest sugar? and then feed sugar? Never—no, sir; I'll let 'em die first.

Give my best wishes to Ernest. I wish him Godspeed. 9—GEO. A. WRIGHT, 55—95.

Glenwood, Pa., Jan. 15, 1886.

"SUCCESS IN BEE CULTURE."

PROF. COOK'S OPINION OF HEDDON'S NEW BOOK.

EDITOR GLEANINGS:—I know you too well to even doubt but that you, like myself, will believe and read with great pleasure and satisfaction this *brochure* from our friend Heddon. From the very nature of the case, my book gives prominence to the scientific aspect of bee-keeping, and to such practical questions as are more closely related to general science. You, as an editor and dealer, have ready access to the people, and know just what they are feeling after, and must constantly be working to give them better and cheaper implements, and so the A B C has its special mission. But our friend Heddon, as a large and experienced producer, is emphatically a practical man, and is dead in earnest in his search for better and cheaper methods. As one of our ablest, most successful, most studious bee-keepers, we all expected his book to be replete with valuable facts and suggestions, and we are not disappointed.

My brother said to me the other day, just after completing the reading of this book, "I have received a large number of valuable hints, and some way they are so in the line of my own experience that I feel certain they will prove practical and very valuable." I have read the work with great care, and I feel that no wide-awake apiarist can spend 50 cts. more profitably than in securing this book, and so I am prompted to write this notice.

The general appearance and mechanical part of the work, and especially the clear, terse, and forcible descriptions, will meet no criticism from the intelligent, practical bee-keeper. The first part of the book is not greatly different from like portions of other similar works. Mr. Heddon and his anonymous "friend" explain what actual experience proves most valuable with them, and do not obscure and puzzle with descriptions of many things and methods. While this plan has much to commend it, we must still remember that this is a great country; and in so intricate an industry as bee-keeping, what is admirable in one location may be worthless in another. This caution is, however, repeatedly urged in the work.

We are specially interested in the chapter on hives, and the explanations in regard to the securing of comb honey. The former has been a matter of long and earnest study with the author, and his success in the latter makes him an authority. Surely no one will say that his hive, his method, or his manipulation is copied. For the past two years I have been experimenting with this reversing business, and am fully convinced of its excellence; and though I had no time to plan or speculate on a reversible hive, I had expressed the opinion and belief that it was a desirable implement, and sure to come. I have little doubt but that Mr. Heddon has given us a desirable improvement, and I shall try it the coming season with full assurance of success, and of improving old styles and methods. The contracting of the brood-chamber at times, I know to be very valuable. This ready means of its accomplishment will commend itself to those who have studied and thought in this direction. The honey-board and bee-spaces, no one will abandon who has given it a fair trial. With the ease of reversion and contraction, the bee-spaces and honey-board, and ability to at once invert sections, we have comb-honey production reduced to a science.

There are, however, some things to criticise. We did hope our friend would outgrow his morbid notions about "swelling our ranks," and "specialists," before he wrote this valuable work. We are sure the increase of demand has more than exceeded the increase of supply. Wife tells me, that during the war she paid 60 cents for very poor cotton cloth, while the best sells to-day for 7 cts. In 1870 the same cloth was 18 cts. per yard by the bolt. Since I have kept house, fifteen years, sugar has declined more than one-half. Thus honey is no exception; and does not Mr. Heddon and everybody know that high prices make brisk trade and eager buyers? True, people did run after honey fifteen years ago, and so did they after fruit and all commodities. Do they to-day? As long as I know of scores of amateur bee-keepers who are securing pleasure, health, and profit, from their bees, I shall still take issue with my friend.

There are a few minor points, like function of drones, stimulative feeding, etc., that I feel to criticise; but on the whole the book is admirable, and should, and I trust will, be at once in the hands of every enterprising bee-keeper in the land.

Agricultural College, Mich. A. J. Cook.

I believe, friend Cook, I can stand with you in every thing you have said. Every bee-keeper who wants to be up with the times should read Heddon's new book.

"SUCCESS IN BEE CULTURE."

FRIEND ROOT'S CRITICISMS.

After what we have heard from others regarding our little book and the new system of management for comb honey, and new hive adapted thereto, your remarks on page 45 may have a wholesome tendency to prevent our becoming vain. I suppose we are all fond of praise. I believe we all ought to be. I hope never to sink so low as not to feel a thrill of pleasure when receiving that praise which I have endeavored to merit.

Or who would even care to do brave deed,
  Or strive in virtue, others to excel,
If none should yield him his deserved meed,
  Due praise, that is the spur of doing well?
For if good were not praised more than ill,
None would choose goodness of his own free will.

I believe it is neither honest nor wise for us to feign indifference to the good opinion of others, or their candor in expressing that good opinion. I believe with the poetYoung, that,

The love of praise, howe'er concealed by art,
Reigns, more or less, and glows in every heart;
The proud, to gain it, toils on toils endure;
The modest shun it but to make it sure.

Still, we do not expect praise from every one. I do not now call to mind the history of any person who did, or even endeavored to bring about any reform, either in social, moral, or business life, but that made opposers, and sometimes enemies thereby. Greville tells us that "those men who are commended by everybody must be very extraordinary men; or, what is more probable, very inconsiderable men."

The above is not said with a belief that in your remarks on page 45 you endeavor to "damn with faint praise," as Pope says; yet after we have endeavored to present the best we know, both in mechanical construction and manipulation in the apiary, looking from our standpoint it seems as if you had misconceived something in your forced, hasty review of the book and new hive; and as these subjects are just now greatly interesting many readers, and have been paramount with me for more than a year, I ask for space for a fair and candid explanation.

I appreciate your sympathy regarding the trouble we have with the engravers, and thank you for your words of praise for the author, and am glad you did not say the book was not worth the price asked. I have seen many essays upon apiculture, that I considered worthless to any one, and worse than worthless to many; but I never saw a book devoted to our business that was not worth many times more than the price asked.

You say you "think the book should be read in connection with other works," and give your reasons for so believing, both of which are entirely correct; and I thank you for the reasons given, than which nothing more commendatory need be said on that point. You say, that to you the main feature of the work is the new hive. Were the book handed to me a stranger, I should look at it just as you do; 18 of the 228 pages are devoted to that subject; and if any reader should infer by your remark that the book was a part of the new hive, rather than a description of the new hive being a part of the book, I would call attention to father Langstroth's work, and the further fact of the proportion of importance of the hive as compared to all else related to bee culture.

You next say the new hive is to throw the old one (*i. e.*, our modification of the Langstroth) entirely aside. If you mean in principle, that is just the way it looks to me; but if you mean that sentence to be taken literally, in its broadest and most extravagant sense, for the benefit of some of your readers, please allow me room to explain. I have tried to exercise care not to say any thing that might lead any bee-keeper astray.

It is not human to be always right; and whatever I may have said that tended to lessen the income of any bee-keeper I deeply regret, and assure you that my intention was exactly the reverse.

I do *not* advise any one to exchange a good hive for a better one, in a rash and hasty manner. But few of my present 450 colonies are in the new hive, and I shall make the change only as fast as economy will warrant. My thousands of straight all-worker combs in reversible L. frames will not be sacrificed. This thought should have been in the book; but we shall be thankful that our journals may supplement our books, as my little work is intended to supplement the more comprehensive works of others. Is it strange that the little "Success," like its author, should be a specialist?

You speak of your thoughts of years ago of a case without frames, with top and bottom bars for many of the purposes of my new hive. These same thoughts I entertained during the evolution of the new hive; but I found that, to make the system complete in *all* cases, the combs should be movable.

You say it is a little amusing to see me go back and declare in favor of wide frames and separators. That statement amuses me. I presume you have been too very busy to have noticed that in my writings for papers I have favored them some two or three years when used one story, upon the tiering-up plan. I was driven from their use, as well as the hundreds who went with me, from our experience with them in two-story supers. I was led to the use of them again some four years ago through the solicitations of Mr. Oatman, and announced my success and pleasure with them as fast as experienced. I must change every week, if 'tis necessary to progression; but I think you have covered me over a little too deep in this instance. You did not mention the peculiar features adapting the horizontal parts to reversing in two different ways. One, by having a half bee-space on either side of the frames in each case and the honey-board, and of having all of the bee-space on one side, pushing the frames through at each reversion.

Yes, this shallow hive is not only "splendid for shipping bees," but owing to its depth, weight, character, and fixedness of the combs and the cases, it is splendid to move anywhere about the apiary, or in a repository, as well as to the railroad station. I now come to your objection to the tiers of series of shallow combs; and I must say that I can not believe that you have had experience upon this point. From the standpoint of my experience, it astonishes me that any one should think that queens will not breed rapidly in shallow combs. I feel sure that this is the echo of the same frightened tones that were loudly heard when father Langstroth took his grand step from box hives 18 inches tall to his "dangerous shallow hive." You speak of "less than 5 inches of comb depth." My combs are only ⅛ inch less, and my experience has firmly convinced me that I can take two tiers of combs, no more than three or four inches deep, and all of 24 to 30 inches long (to get capacity), arranged with the "sticks and spaces" as mine are, and, by the *interchanging*, can encourage breeding faster, with less expense, than can be produced in any other way with any depth of combs; or I will just let the two cases alone, and agree to equal in brood any other form of hive, all other influences being the same. We know this by hundreds of experiments; and friend Bingham, withh is 25 years' experience with colonies, in hives containing eight combs 4½ inches deep and 22 inches long, believes that, in these combs, brood is produced faster than in any other form.

I have used one of his hives eight years; and as far as my observation goes, on the one hive, I would say the shallower the better, for brooding.

Do you forget how our queens often produce twice the brood in two or three tiers of L. frames (passing honey-boards and perforated bottoms) that they will in one tier, even though that one be large enough to hold all the brood, if it were all concentrated?

Do you forget the rousing swarms from old box hives full of cross-sticks, with the combs all in jags and pieces, which have oft and repeatedly been praised for the winter passages they create? You did not mention the adaptability to contraction, so highly prized by friends Hutchinson, Doolittle, and others, bringing out the fact that only one section or brood-case is used during the greater part of the year.

A WORD ABOUT MY PATENT.

Regarding the originality of my invention, you have spoken quite correctly in one sense, yet I fear you have left a wrong impression. I knew that closed-end frames were old; also that, though I was an original inventor of screws for tightening frames, others were original in the idea before me, and that it is not patentable.

I am also aware that I am not original in using frames around bee comb, nor of honey-boards of some kind, nor of using wood for bee-hives. I don't believe there is a man in the world bright enough to make an improvement in hives, harvesters, sewing-machines, watches, and, I might say, nearly every useful article known to man, without using old parts mainly. If he has one new feature, or a valuable combination of old ones that will carry into effect a new and useful system, he does well, and at once commands my respect, and the earnest attention of the Patent Office. All, yourself among the number, have credited to me a new and original system of management, and the new hive is a peculiar combination of parts and principles intended to be best adapted to working that system, and that combination is what we have endeavored to secure by letters-patent. If the new hive and peculiar system of management are worthless, a patent can do no harm; if useful, should I have no part of the value thereof? In my chapter on patents I endeavored to make these points clear. If my reasoning is unsound, I should thank you for correction. If I have not already given enough of value to the public to amount to my full share in the line of presents, I here ask you to publicly tell me so.

I shall be pleased to send you a complete hive, and enjoy seeing some accurate illustrations of it. Wouldn't it be well to allow me or friend Hutchinson to explain its workings, and the system of management adapted to it, we and my students being the only ones who have passed it through the crucible of practical experiment?

Dowagiac, Mich. JAMES HEDDON.

Friend H., I shall be very glad to have you write an explanation to the engravings after I have had them made; in fact, I greatly prefer you should do so, as I, of course, have had no experience as yet in using such a hive with bees in it.

THE STINGLESS BEES OF MEXICO.

THEIR MANDIBLES A MEANS OF DEFENSE.

I THOUGHT it might not be uninteresting to your many readers to have a short story concerning the little stingless bee of Mexico; and if you will bear with me I will tell you what I have learned through the many travelers whom I have seen and conversed with on this to me very interesting subject. I have a brother who sojourned in the sunny clime of the State of Sineloa for a little more than one year. He says they are very numerous. He says he was out in the woods shooting birds, called by the natives chichilacs (a bird something like the guinea in size and habits), and when they had fired their guns off, and were reloading, his companion said to him, "When we get our guns loaded we will have a bait of honey."

My brother was surprised, for he had not, during all his stay in that country, seen either bees or honey; but when their guns were reloaded his companion looked him straight in the face, and, smiling, kicked a small chunk of wood with the toe of his boot, and, bursting it open (it being hollow), to his surprise it contained between one and two quarts of the most beautiful and delicious honey it had ever been his good fortune to see and taste. The honey was stored in combs constructed of wax, and were in every particular just like the combs of our honey-bees, except the cells were very small. He describes the bees as being not larger than common house-flies, and marked something like yellow-jackets.

After having once seen the bees, he had no difficulty in finding more than 100 swarms during that day. He says he counted 25 swarms in the hollow roots of one wild fig-tree. Afterward he often enjoyed the luxury of eating the honey stored by these interesting and wonderful little bees. Other travelers give a similar history; and all say, that, though the bees are stingless, they are not left without courage and means of defense. Their mandibles being sharp they can bite in a manner that is "more forcible than pleasant."

The Mexicans, who live in our town, often talk to me about the *colmanus* (pronounced *cole-mah-noos*), as they are called in the Mexican vernacular. They say they are "*muy brava;*" that is, they are very brave. I hope ere long to be enabled to visit that country, and study the habits of that wonderful little insect.

Tempe, A. T., Jan. 11, 1886. JOHN L. GREGG.

Friend G., we are very much obliged indeed for the very valuable information that you give in regard to these little bees that don't sting; and we place $10.00 to your credit for the article, to help enable you to make further researches in this matter. The same bee, if I am correct, has been tried here in our northern climate, but they don't seem to stand the winter. Do you think the honey would sell in our markets—that is, does it compare favorably with the honey of our native bees? Do you think they would work in movable frames? Perhaps the matter can be tested better in their native clime, and I will willingly pay you for the time and trouble required to test the matter, if you are willing to undertake it. If your brother had no difficulty in finding more than a hundred swarms during that day, it seems to me that locality must have been a wonderful field for modern bee culture. If you could send us a piece of the comb by mail we should be very much obliged indeed. May be you can send us some bees in a queen-cage, either dead or alive.

FEEDING BACK NOT PROFITABLE, AND WHY.

FEEDING 3500 LBS. OF EXTRACTED HONEY TO GET IT INTO SECTIONS.

ON turning to page 443, GLEANINGS for July 1, 1885, we find a communication regarding the feeding-back of extracted honey for producing comb honey. Bro. Hutchinson seems to advise the use of separators, and announces that the bees will otherwise even bulge the combs, and build projections and little mounds upon the surface of the combs. He has also met some incidental troubles in feeding back for sections. I have had some three seasons of experience in this feeding-back business, but more extensively the past season. We would say that no separators were in use, and never have our bees produced a finer lot of comb honey than was the one produced by this feeding-back method during the past season. The combs were bright and clean; the sections were filled. There was a few sections which were very slightly bulged. There was not one mound or projection, to our knowledge, upon the surface of any of the combs. We shall be glad to give you our opinion as to why feeding back is unprofitable. Here is the whole business: Twenty of our strongest colonies were selected for this feeding-back purpose. The 20 colonies would not have exceeded 200 lbs., or an average of 10 lbs. per colony to each brood department at the commencement of feeding back, which was comparatively near at hand, Aug. 17, 1885. Many large feeders were made, holding 25 lbs. each. Two sets of sections were placed on each hive, and no more. To the above 20 colonies was fed 3500 lbs. of extracted honey, or an average of 175 lbs. per colony, in 35 days. The total amount of comb honey received from the 3500 lbs. was only 1250 lbs., or 62½ lbs. per colony all in one-pound sections. The total amount for the 20 brood departments was 800 lbs., or 600 lbs. of the 3500 lbs. of extracted honey stored in the 20 hives. Thus the consumption for the 20 colonies in the secretion, or forming of wax scales, and for brood-rearing, evaporation, etc., is that enormous total of 1650 lbs., or 82½ lbs. per colony. To some of these colonies was fed perhaps nearly 150 lbs., ere the first 54 sections were ready to come off. Only they who have tried this experiment know what difficulties one must encounter by turns, the scores of exasperating stings, and the imperious robbers, with their exciting movements and the taking off and refilling of each feeder. All this is certainly enough to disgust one in feeding, to say nothing regarding the loss in the operation. The increase on these 20 colonies is nearly 100 per cent; and as they were used mainly for building up late colonies, this is quite an item.

A. F. UNTERKIRCHER.

Manchester, Mich., Jan. 8, 1885.

Friend U., you have given us the report of a very valuable experiment indeed; but, why take so many colonies? You will see by the experiments I give in the A B C book, that much of the honey will be saved by making two or three of the colonies do the work. Perhaps, however, this would have been impossible with so large an amount as you had to feed back And, by the way, the results of your experiment will be a good fact to furnish the newspapers that are accusing us of feeding cheap syrups and calling it honey. Counting time and all, it probably will never pay anybody to feed sugar, even if it would make nice honey, and I very much doubt if it ever has been done to any extent worth mentioning. I have noticed exactly what you say about robbers' exasperating stings, and the unnatural aspect of affairs induced by this kind of wholesale feeding. It seems to me I never in my life encountered any stinging, or any thing about bees, so terribly ugly as when feeding to get sections filled. The bees themselves seem worried and unnatural; and if the weather is very warm, it seems just about out of the question to do any thing about keeping robbers from pushing their way into the entrances of these hives containing large feeders.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER II.

FAMILY TALKS ON BEES.

THE morning after the bees had been removed to the parsonage, Mr. Meek called Jane and Tommy into his study for a talk.

"Now," says he, "you have bees to care for; but, what do you know about bees? Tommy, you may answer first."

"Well," says Tommy, "bees are living things. I think they are called insects, but I am not sure. A great pile of them live together in a box, or nail-keg, or, when wild, in the woods they live in hollow trees. They make honey and wax, and sometimes sting people. Jimmy Brown told me that in every hive there is a king-bee, a great big long bee, that bosses the other bees, and makes them do just as he wants. I guess that is all I know about them; only that those who keep bees manage in some way to get honey from them. Some people kill the bees with brimstone, as Mr. Brown was intending to do with ours, and thus get their honey; but other people can get their honey without killing the bees. I do not know how they do this; but I want to learn, because I do not want to kill a single bee if I can help it."

Mr. Meek then asked Jane to tell what she knew. She replied, "I know very little more than Tommy has told you. I am sure bees are insects. Early this morning I went out to look at our hive. I found two bees dead before the entrance. I brought them into the house, and looked at them through our magnifying-glass. My teacher says, 'Insect means, to cut into, and is applied to certain living things because they seem to be nearly cut in two.' I saw that the heads of those bees seemed almost cut off; and back of where their wings are joined to their bodies, they are almost cut in two again; so I feel certain they are insects. I also learned in some place, that it is not true that bees have a *king*, but they *do* have a *queen*. She is the only truly female bee in the colony. She does not boss the other bees, but merely does her part in the colony, which is to lay all the eggs that are laid. Then I do not think bees make honey; God makes it come in flowers, and the bees only gather it. I also know that bees swarm; when there are too many bees in a hive they divide, and part go out to form a new colony. When they come out they fly around for a time, and then gather in a bunch on some tree or limb, where they look like a large ball. If their keeper sees them come out, and puts them in a hive, they are likely to stay; but still, sometimes they leave his hive, and go to the woods. If he does not see them they will remain for a time on the limb, or wherever clustered, and then depart to the woods. That, I guess, is all I know about bees; but I should like to learn more about them."

Mr. Meek laughed a little as he replied, "I see you know as much about bees already as many men do who have kept bees for years; but there is still much for you to learn. If a man wants to raise horses successfully, he must study about horses; if he raises hogs he must understand them; and I assure you that no man can manage bees successfully unless he understands them. I want you to learn what you can about bees before next spring. Many years ago I read about a minister named L. L. Langstroth, who had studied much about bees, and who had written a book on the subject. I bought his book, and was well pleased with it. Here it is, and I want you both to read it carefully. For two years I took a farmers' magazine which came once a month. I noticed in each number a page or two devoted to bee culture. I carefully preserved all the numbers; here they are. I want you to hunt up in each one the pages on bee-keeping, and read them carefully, and bring to me any thing either in the book or papers you do not understand, and perhaps I can explain it to you."

The children gladly accepted the book and magazines, and began to peruse them. For a time, at least, much of the talk at the minister's table, when strangers were not present, was on bees and honey. We might for a little listen to some of their talks.

Mr. Meek said, "Well, children, what about bees to-day?" Jane replied, "In reading I find the word *apiary* very often; but I do not know what it means."

Mr. Meek replied, "*Apis* is the Latin name for bee; apiary means a bee-yard, and comes from that word."

Tommy asked, "Is our yard an apiary?"

His father replied, "I think hardly. If we should call a single colony, and that a weak one in an old nail-keg, an apiary, we should be putting on too much style. But I hope, if our bees live, to see you and Jane owning enough colonies to call our yard an apiary."

Jane asked, "If our bees increase until we have a great many colonies, perhaps fifty or one hundred, will they all belong to Tommy and me?"

Her father replied, "Yes, certainly; Mr. Brown gave them to you and Tommy, and I intend that you shall keep them and all their increase. My reason is, I want to teach you to work for yourselves. In a few years, almost before you know it, you will have grown up, and will have to work for yourselves; so I want you to commence now, and learn how to work and do business for yourselves. As you are going to do business, you need a book to record the business you do. Here is a small blank-book which I do not need. It will answer for the present, and I want you to record in it every item of expense and income. You will own these bees together; that is, you two will be a firm, or company, doing business together. Now, by what name shall this firm be called? The large brick store in town has on it, John Morgan & Brother, which means that John Morgan and his brother Samuel are a firm doing business together. Just so, Jane and Tommy Meek is a firm now formed to do business in bees and honey; and what shall we call this firm?"

Tommy replied, "Call it the firm of Jane Meek & Brother."

Mr. Meek wondered that he did not say the firm of Tommy Meek & Sister, which is what many boys would have said. Taking a pen, he wrote in the back of the blank-book, in a large hand,—

ACCOUNT-BOOK
OF
THE FIRM OF
JANE MEEK & BROTHER.

He then said, "Now that the name is settled, tell me what you are learning from reading the book and papers."

Jane answered, "We are learning many wonderful things, things I never should have thought of unless I read them. Bees are very strange insects, and do some strange things. In May, June, or July there are often forty thousand bees in a hive. Just think of it—*forty thousand!* But there are not so many during fall and winter; and in the spring some colonies have very few."

"Yes," says her father, "sometimes colonies have not a single bee in the spring. They continue to grow fewer in number, until there are none at all. Tommy, have you learned how many kinds of bees are in a hive?"

"Yes, sir, there are three kinds—the queen, a large long bee; the drones, large bees, but not long like the queen; and the worker, the small busy little fellow that gathers the honey and stings people. The queen has a sting, but does not sting people. When she meets another queen she fights with and stings her. The drones have no stings. You can catch one and handle it as you would a fly. I should like a colony all drones, then I should not be afraid to work with it."

"But, Tommy," replied his father, "I fear it would be a very unprofitable colony. A man, who commenced farming, wishing to raise turkeys, bought a pair from a farmer. It being late in the spring, the farmer asked more for hens than gobblers; and the buyer, seeing that the gobblers were much larger than the hens, took a pair of gobblers, but failed to find any turkey-eggs that summer. The drones are the males among bees. They are found in the hives only during the honey season. At the close of the honey season the worker-bees kill them."

Jane said, "I have learned that the most important bee in the hive is the queen, or the mother, as she might be called. She lays all the eggs. She lays eggs very rapidly, laying three or four a minute, sometimes three or four thousand a day. But she never lays very many eggs unless the bees are bringing in plenty of honey. In the cold winter months she lays hardly any. Every bee has its work to do. Some build the combs, others fly in the fields, searching for honey or pollen, others are nurses, and care for the young, while some stand as guards around the entrance."

"But," says Mr. Meek, "did you learn from the books how to winter bees?"

"Yes," said both children, "we read about it;" "but," said Jane, "I hardly know what is best. Some people carry their bees into nice warm cellars, where they are kept snug and warm all winter; still, some who do so lose their bees. Others leave their hives out unprotected all winter, standing just where they did during the summer; and, what seems very strange, sometimes their bees winter better than in cellars. This, in the papers, is called wintering unprotected, upon their summer stands. Some winter by leaving their hives upon their summer stands, and packing straw and hay around them to protect them from the cold; others write frequently about wintering in chaff hives; but I do not know what kind of a hive a chaff hive is."

Her father said, "I now remember that once when away from home I saw several very large-looking hives; and on inquiry I learned that they were chaff hives. I inquired how they were made, and was told that they consisted of two distinct hives, with a space between, which was filled with chaff, packed in closely, thus keeping the inside hive from the frosty air, and keeping it warm."

Here Tommy expressed his opinion that their bees would winter best in their nice warm cellar, adding that he had been reading that those in the cellar wintered on much less honey than those exposed to the cold. His father also favored wintering them in the cellar, but advised letting them remain on their stands until winter had set in, and until it seemed evident that the pleasant autumn weather was ended. He said it did bees good to have flights during winter, and that was why those left on their summer stands sometimes wintered better than those in the cellar. In winter they have flights occasionally, while the lack of those flights causes those in the cellar to become diseased.

Jane said, "I am glad our bees will be in the cellar during the cold stormy weather. I do not think I could sleep, cold winter nights, when the wind is driving the snow, and the thermometer is at zero, if our bees were out in the cold. Our horse has a warm stable, so has our cow. The chickens have a warm comfortable coop, and even our pig rejoices in good quarters. Why, then, should we leave our bees out in the cold?"

"But," says her father, "you forget, Jane, that all bees are in a house. Their hives are their houses."

"But, pa," said Jane, "I think an old nail-keg is not much of a house."

To be continued March 1, 1886.

THE SOLAR WAX-EXTRACTOR.

MORE SUGGESTIONS REGARDING IT.

I DO not know whether or not I can add any thing useful to the question regarding the solar wax-extractor, which seems now to be prominent, but I will give my experience in this direction, and some suggestions.

I made a solar wax-extractor the past season from the plan furnished by Mr. Poppleton, with some modifications. My box is 28×42 inches, outside measure, and 12 in. deep, with straight instead of zigzag bottom. The tray is made of wood, with a rim extending 1½ inches above its surface, except at the spout where the wax runs off. This is sheathed with tin, and is made just wide enough to slip inside the box. It carries its width for 20 in., when it slopes for about 14 in., a space of 6 in. being left for the wax to flow off.

It is covered with double glass, composed of 4 sheets 20×26 in. The tray is hinged near the back end by a couple of short pieces of stout wire run through the sides of the box into its edges. This admits of the front end of the tray being raised to lift the pail, which holds the wax, in and out.

This tray is large enough to hold the cappings of a day's extracting. Having drained during the night, they are put into the extractor the first thing in the morning; and if the sun is ordinarily strong they are melted before night. The wax is left in the pail till the next morning, when it will be found in a solid cake, floating on the honey which has run off with it from the cappings.

I purpose making some changes in my extractor, which I think will improve its workings. The sides of the box cast a shadow on the wax for several hours in the morning and afternoon, unless it is shifted about to face the sun as it advances. To do this the more readily, I intend to fix it on a frame made to revolve on a pivot. I find, moreover, that my extractor develops heat enough to scorch the honey which goes off with the wax, so that it is nearly spoiled, even for second-class honey. Perhaps perforated tin, as it is used in the extractor described by Mr. Muth-Rasmussen, on page 339 of GLEANINGS for 1885, would remedy this evil. The capacity of the tray might also be increased by having its width uniform, and having a gutter to catch the melted wax, this gutter having a slight fall from each end to the center, where a hole in it would permit the wax to fall into a pail.

Further improvements might be made by having the legs which support the end of the extractor fixed with a thumbscrew so that it could be supported at any height. A similar arrangement attached to the hinged end of the tray might correspondingly regulate its incline. Thus the position of the glass might be readily changed so that the sun could strike it at right angles at all times. As there are days nearly up to November when the extractor may be used, this is a matter of importance.

With these suggested changes I think that the convenience and efficiency of the sun wax-extractor, as I have used it the past season, would be greatly increased. Mine, as it is, I consider one of the most useful things which I have about my apiary, and I would not be without it for twenty times its cost. Heretofore the storage of cappings, till I had time to render them, was fraught with vexation. They would drip, drip, no matter how well they might be drained; and unless a tin receptacle were used, I would soon be reminded of the searching and sticky qualities of honey by finding a strain of it making its way over the floor from under my barrel of cappings. But there is no vexation of this sort now, and I thank Mr. Poppleton for his plain directions which led me to make a solar wax-extractor. JAMES MCNEILL.

Hudson, N. Y., Jan. 16, 1886.

Friend M., there is a simpler way of getting the sun's rays in the morning and evening than having your box on pivots so it must be turned. Use three or more panes of glass. Have one side at an angle southeast; the middle one at an angle facing the south, and the third at an angle facing the south-west. Or, to get a more perfect arrangement still, use a bell glass in the shape of a rounded comb or pyramid. I am astonished to know that the heat of the sun could injure the flavor of the honey. Some arrangement to let it run off before it is so hot would surely remedy this. In regard to having drippings or cappings, or any thing else, running down on to the floor, I would not have any such work about me. If those who help about the apiary can't be cured of such tricks, I would swap them off for somebody who *could* be cured.

A REPORT FROM TEXAS.

SWARMING-OUT OF NUCLEI.

I TOOK two colonies on shares three years ago last spring. I now have 35. I increased mostly by artificial swarming. I believe it is the best way, unless one could be in his apiary all the time during the swarming season. I made 7 artificial colonies this last summer, every one of which swarmed when the first queen hatched out. This is something I never knew before. I thought at first it was on account of their not having any unsealed brood. I gave them young brood and larvæ, but it did no good—they swarmed all the same. Of course, if I had given them a laying queen when the colonies were first formed, the trouble would have been over. One colony I gave a laying queen when formed, and I took over 100 lbs. of honey from it. The others all swarmed, and filled their hives, but made but little surplus.

EIGHT DEGREES ABOVE ZERO, IN TEXAS.

We are having cold weather here now—eight degrees above zero, which is uncommonly cold for this country.

COMBS BREAKING DOWN BY FREEZING.

I noticed this morning, while looking through my bees, that the honey was running out at the entrance of several of the hives; and on examination I found that the combs in the outside frames were cracked, and the honey oozing out. This is something else I never saw before. I've seen combs melt down in all kinds of hives, but I never saw them *freeze* down before.

DANGER OF LEAVING AN UPPER STORY ON DURING WINTER.

I have lost one colony this winter. It was a strong one, but I had left the upper story on, and they went above and starved to death, with at least 40 lbs. of nice honey in the lower story. Every frame in the lower story is solid sealed honey. So you see the loss of this colony is attributable to my neglect, for I know very well that bees could not winter, even in this climate, on all sealed honey. This is a good country for bees. We have a great variety of honey-producing plants. The horsemint is the best honey-plant we have here. A good many people keep bees here, but there are very few who take any pains with them. Most of them hive them when they swarm, set them in a fence-corner, and that is the last of them until robbing-time.

J. W. THOMPSON.

Decatur, Wise Co., Texas., Jan. 19, 1886.

Friend T., it is certainly very unusual for the bees of a nucleus to go out with the young queen, when they have brood in all stages in the hive. Of course, a laying queen would set things so much ahead.—One hundred pounds of honey from an artificial colony is pretty well, for a beginner. I think your locality must be a good one.—Eight degrees above zero is certainly colder than I supposed it ever was in Texas. No wonder your combs broke and let the honey run out. A chaff hive would effectually remedy all such troubles, and I should most assuredly recommend chaff hives in Texas, if you are going to have a repetition of the temperature mentioned above.—Bees are always liable to go into the upper story where it is left on all winter, because the warmth from their bodies rises naturally, and they follow in their efforts to cluster in the warmest place in the hive. Here is where the advantage of the Hill device comes in. It makes a cavity covered on all sides by the chaff cushion. Now, this chaff cushion allows air to pass through fast enough to keep it always pure, and at the same time it holds it long enough so the heat of the hive may accumulate in this cavity, inducing the bees to cluster right there, with their stores of honey so near them that they are always able to reach it.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

ROAD DUST AS POLLEN.

BEES do actually gather dirt for food. Here is what I copy from my "Bee-Book of Items," dated April 13, 1884.

"Bees are working lively to-day, and yesterday, after a confinement of a week of cool weather. They are carrying in water and dust from the road."

I never saw bees gather dirt but this once, and perhaps it was a week that they worked on it. They packed it just the same as they do pollen. It was on account of frost and strong winds destroying the pollen from the trees that had been yielding pollen before, and, of course, they quit the dirt as soon as they could gather elsewhere. I offer this in reply to you on page 10, Jan. 1. Bees seem to be wintering well so far, as we have had a very mild winter up to date. JOHN A. THORNTON, 73—108.

Lima, Ill., Jan. 7, 1886.

CAN POLLEN BE ARTIFICIALLY REMOVED FROM CELLS?

Please tell us if there is any convenient way of extracting pollen from old combs. Last summer I filled my hives with combs where bees had died the previous winter, and there was a large amount of pollen in them. Will it prevent the queen laying—that is, will the bees clean the cells in the brood-nest, to make room for the queen to deposit her eggs? or, should such combs be taken from them next summer, and others supplied with foundation be put in their place? Is it certain that they use much pollen through the winter, if they have a plenty of honey? Is it right to cut out all the drone comb in the spring, and keep it out of colonies that you do not wish to breed from? These are questions that I don't recollect seeing answered in the A B C.

La Otto, Noble Co., Ind. E. S. HANSON.

The subject of removing pollen from old combs was up several years ago, and I believe we had one or two communications to the effect that steaming them in a wash-boiler, or some other similar way, till the pollen was quite soft, would enable one to throw it out by means of a honey-extractor. Of course, one must take pains to avoid melting the comb. In our locality we never have too much pollen; that is, when brood-rearing commences in the spring, by distributing the combs of pollen among hives rearing brood largely, we get it all worked up into brood without any trouble. I do not think much pollen is used in the winter, unless brood-rearing is going on largely.—Your question in reference to drone comb is answered by friend Dadant in another column.

THE STANLEY EXTRACTOR.

We have made some slight improvements on the extractor you saw at Detroit, but no great changes, as we think they are now about good enough for practical purposes. We intend to start a branch shop somewhere near Kansas City during the month of February, so that our friends in the South and West may avail themselves of a chance to get a machine at a low rate of freight. G. W. STANLEY.

Wyoming, N. Y., Dec. 19, 1885.

FURTHER FACTS REGARDING FRIEND HOXIE'S HOUSE-APIARY—P. 744, 1885.

As some one may build a house apiary like mine, perhaps I ought to explain it more fully. Those doors with glass in them are not for the purpose of excluding bees or getting them out of the house. They are only for giving light and warmth in cold weather; when the house is opened, no bees ever get on them. I planned my house especially to meet the objection you raised. In opening the hives, the bees fly on to the screen doors; as there is no other place the light enters, all I have to do is to swing the door around against the side of the house with a little jar, and they immediately fly off. I have tin spouts through the house between the hives, which I forgot to mention, and were put in after I got my bees in the house. These spouts are pieces of tin rolled up and put through a 1½-inch auger-hole, level with the floor, and project outside 1½ inches. They are cut with a couple of projections on opposite sides, which are bent over against the inside of the house, and nailed with two tacks. These spouts are closed on the inside with short plugs, with a nail in the end to pull them out by. In order to have the bees that get on the floor go out of these spouts, the tin passageway where it meets the house must be made tight with putty or thick paint, so the light can not shine through, or they will try hard to get out there. In putting up my bees for winter I made, out of pieces of barrel-hoops and pieces of barrel-staves, an article something like the Hill device, which I put under the cloth, and have the covers off; the upper story and all around the hives are filled with dry leaves.

Holloway, Mich., Dec. 1, 1885. H. S. HOXIE.

We have tried similar expedients, friend H., to get the bees out of the house-apiary; but the universal conclusion, by myself and all the hands, is, that it is a good deal simpler and easier to have the bees outdoors where they do not have to be chased after when they get outside of the hives. Although our house-apiary cost several hundred dollars, it stands to-day without a bee in it, and probably will so stand for many years at least.

PACKING POLLEN ON THE HIND LEGS; HOW IT IS DONE.

I have been much interested in your articles on the honey-bee, and in your description of "how the bees back the pollen on their hind legs." You appear to have some doubt just how they manipulate, as their motions are so quick; and I just want to say, that you have got it about right. Now I will tell you what I saw with my own eyes. While visiting at one of my neighbor bee-keepers we were looking through some of his hives and we detected the smell of pine tar. In looking more closely we found that the bees had been using the tar in the place of propolis, and the next question that came up was, "Where did they get the tar?"

TAR AS A SUBSTITUTE FOR PROPOLIS.

"Well," said my neighbor, "the big wagon that we have been hauling stoves on is standing down by the barn, and it has been lubricated with tar, and we will go and see if they are at work at the tar business now."

When we arrived at the wagon there were several bees about the hubs and spindles of each wheel, so we concluded to watch and see how they managed to carry the tar; and as the tar was quite stiff and black we could detect every movement. The bee did not frisk and dodge about with his wings and tail up as they do when gathering pollen, but settled right down to business, biting and twisting away at a little pellet of the black tar; and as soon as he had it in the right shape to suit him, he snatched it from his mandibles with his fore foot, passed it to his next foot, and that foot stuck it in the pollen-basket and patted it down with several strokes. Now you have an idea about how fast Mr. Bee handles his feet; but the pellet of tar was so large and black, the bee at rest, and the sun shining brightly, that we saw with our own eyes, and we both agree that the foregoing is correct.

Valley, Ky., Jan. 16, 1886. G. F. HESELTON.

Thank you, friend F., for so carefully watching the operation. I have seen bees take pellets of wax, but could never witness the action of the middle leg in depositing it in the pollen-basket; but I was anxious to ascertain just how this middle leg grasped the pollen or wax. Did you notice whether the foot of the middle leg, or one of its joints, picked up the little pellets, and transferred them to the hind leg? ERNEST.

A REPORT BOTH ENCOURAGING AND DISCOURAGING.

My bees diminished from 24 to nothing, and my subscription to GLEANINGS has expired. I have enjoyed reading it much, but have yet to learn the taste of nice honey made by my own bees since 1881, when I began with one swarm. I have raised a club for the *S. S. Times*, for 1886, and sent direct to publishers. Thanks for past favors, and best wishes for your future. A. W. VALENTINE.

Bethel, Me., Dec. 22, 1885.

Friend V., we are very sorry to hear that you have not had a taste of honey yet, even with so many bees as that; but we are glad to know that you have dropped off from our list of the *Sunday-School Times*, and have raised a club in your neighborhood. Several have reported in a similar way in regard to the *Times*, and that is what I regard as encouraging; for it can not go into any community without raising the general standard of morals of the people.

LANGSTROTH'S NEW BOOK, ETC.

Mr. Editor:—We wish to thank you for your kind notice of the revision of "father Langstroth's book;" and in answer to inquiries already coming, we wish to state that the revision is not yet half through, owing to our gathering new matter and engravings and information from different parts of Europe and America. The book will not appear before spring, perhaps not till fall. In connection with this work we wish to correct the erroneous idea entertained by some, and found in Mr. Heddon's new book, that we use the closed-end Quinby frame. The frame we use and prefer is the old hanging Quinby frame, made exactly on the principles of the Langstroth invention. The publication of the *new* Langstroth book will be duly advertised in the bee-periodicals, when ready.

Hamilton, Ill. CHAS. DADANT & SON.

THE SOLAR WAX-EXTRACTOR.

I think I have an idea that is good; at any rate, I venture. Take a dish, or rinsing-pan, from your 50-cent counter; solder a tube in the bottom near the side; now place this in a square box with a glass cover. I would have a shelf fixed on the south side of my honey-house, directly under a window. I would use the pan for an uncapping-can, and when it becomes nearly full I would set it out to melt. I am of the opinion that reflectors are unnecessary, also that one glass is enough. The dishpan is just the right shape, and will astonish one to notice the amount of heat they attract. I have, by holding the pan at the proper angle, lighted a cigar in less than two minutes; but of course the heat is diminished when the bottom is covered with wax. I should like to ask if an ordinary tin tea-kettle, with a screw top, would generate sufficient steam to extract the wax in a Dadant uncapping-can. The kettle could be connected with the can by a few feet of rubber tubing. WALTER S. POUDER.

Groesbeck, O., Jan. 3, 1886.

Thanks, friend P., for your idea of the dishpan. Our largest size of retinned, stamped dishpans would doubtless make quite a powerful reflector. We shall probably soon get out a solar wax-extractor that is effective, and does not cost very much money either—may be something made from common utensils we have in every-day use. A common tea-kettle, arranged as you suggest, would, I think, melt the cappings nicely in a Dadant uncapping-can, providing you do not put in too much at once.

A PLAN FOR HEATING BEE-CELLARS.

I desire to present to you a plan for heating bee-cellars, or, rather, modifying the temperature. Place in your kitchen, near the cook-stove, a boiler that any plumber-supply dealer can furnish for $4.00 or $5.00. Pass a pipe from the boiler through the fuel chamber of your stove, and to your bee-cellar pass a pipe around the cellar near the floor, and back again to the boiler. If the cellar is away from the house, place the pipe five or six feet beneath the surface, fill the boiler and pipes, and you will have a circulation of warm water that will nicely temper the atmosphere, and give an opportunity for good healthy ventilation. If necessary, you can supply a cut-off pipe so you can cut off circulation through the cellar, and cool it if necessary; but I should think it better to ventilate well. You can easily keep the temperature at 40° to 50°, and give the bees a good ventilation. As to detail of arrangements, any plumber can give you full particulars.

CHARLES E. PARKS.

Watertown, Wis., Dec. 30, 1885.

Friend P., your arrangement is substantially the hot-water plan generally used for greenhouses and conservatories, only instead of heating a part of the pipe, the *boiler itself* forms a part of the circuit, and the heat is applied through the boiler, or through flues in the boiler, and the only place where the circuit is open to the outer air is at some point in the greenhouse furthest from the furnace. Here is what is called a stand-pipe, to fill up what is lost by evaporation, and also to allow the water to expand and contract by the different temperatures. As soon as heat is applied, a circulation commences. Hot water goes from the boiler out to the stand-pipe, and the cold water goes back into the boiler again. A home-made apparatus, such as you describe, will often answer very well for special case .

PRIZES FOR HONEY AND BEES AT FAIRS; HINTS TO VICE-PRESIDENTS.

During the first three months of the year, the premium-lists for County, State, and District Fairs are usually made up. The Vice-Presidents of the National Society should therefore soon commence their work.

I would respectfully suggest that they communicate with the different Official Boards of the Agricultural Societies in their respective States, and endeavor to induce them to offer appropriate prizes for BEES and HONEY at the fairs for the coming season.

The following, or something similar to it, would be well to recommend in the line of prizes:

Best colony of bees in observatory hive; best display of comb honey; best display of extracted honey; best display of beeswax; best honey-extractor; bee-hive for all purposes; and largest and best display of apiarian implements.

Each vice-president and secretary of State and local societies will understand the requirements of their locality, and act and govern themselves accordingly. H. D. CUTTING,

Chairman of Executive Committee.

Clinton, Mich.

I second your motion, friend C., in the above matter.

BROOD WITH THEIR HEADS UNCOVERED.

On page 51, current volume, Mr. C. C. Miller, in speaking of bees with their heads uncovered, says that he doesn't think they are ever left uncovered unless the wax-worm uncovers them or runs galleries over them. Now, I think differently, for I have seen patches as large as a man's hand, and in several combs in the same hive; also in very populous colonies, which would be very likely to keep the wax-worms at bay.

My report for 1885 is not at all flattering, as the few bees I have didn't make any surplus, and most of them will have to be fed in the spring before they will be able to support themselves from the flowers. LUTHER PURDY.

Killbuck, Holmes Co., O.

Friend P., since you mention it I remember too that it is strong healthy colonies, so far as my experience goes, that leave the brood uncovered during hot weather. I can not think that it was wax-worms in our case.

PARADISE LOST.

Please tell us what Paradise Lost is. I think there are many of our readers like yourself who do not know, but are anxious to find out.

Nappanee, Ind., Dec. 25, 1885. I. R. GOOD.

Friend G., our proof-reader says that Paradise Lost is the immortal masterpiece of that great Englishman, John Milton, the blind poet, who died 1608. Great scholars in all foreign nations have studied the English language, simply that they might read Milton's Paradise Lost, as others have studied it to read Shakespeare. As far as I have read it, it seems to be about Satan and his allies before the advent of man upon the earth; and it makes one painfully aware, when he reads it, that Satan is still making himself busy with the affairs of humankind. The beginning of the book has little more Bible authority than the epistle of Jude and Luke 10:18. It can be had anywhere for 15 or 20 cents. In England it has, we believe, been sold at a penny a copy, which would be about a nickel for us.

BEES STEALING EGGS.

I am still reading GLEANINGS. It is a pleasure to peruse its pages, and get the different ideas. A great deal has been said about bees stealing eggs. Last summer I saw a variety of things that bees are in the habit of doing. I had one swarm of blacks that were queenless. These bees were hovering around the entrance of another hive having a queen, and were picking up things that were brought out. I saw that the bees in the hive which contained a queen were cleaning out some moth webs, and once in awhile they would bring out what I thought were eggs, or something like them, and would let them drop in front of the hive; then these blacks would pick them up and examine them, and fly off with them. Since the subject came up, about bees stealing eggs from other hives, I have been thinking it is just what those blacks were on the search for—to get an egg for a queen. It was in the fall, and I united them to a late swarm.

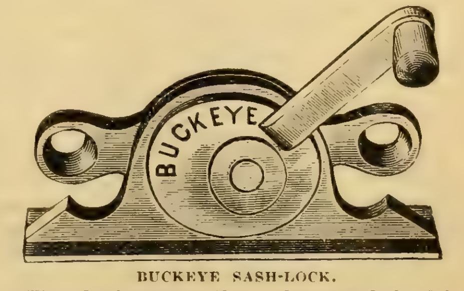
Ashland, O. A. H. BAUM.

Friend B., your suggestion is a valuable one; and since you mention it, it seems that this is the way in which a queenless colony sometimes gets an egg, to save them from utter ruin.

A DEVICE TO FASTEN WINDOWS UP OR DOWN, OR AT ANY POINT.

SOMETHING EFFECTIVE, ALTHOUGH LOW IN PRICE.

FOR many years I have been trying to get something better to hold a window up than a stick or a book, or something of that sort; but although we have tried them, even paying as high as 75 cents per window, I have never had any thing please me so well as the little device illustrated below.



BUCKEYE SASH-LOCK.

This device holds the sash securely by friction in any desired position, as tight as if it were in a vise. It prevents the sash from rattling, and excludes the dust by making tight joints, and yet it does not mar the wood. It is put on with two screws, and can be fitted by an inexperienced hand in three minutes. It works equally well on upper or lower sash, with or without weights. Printed instructions are furnished with each one, as well as screws to fasten them on with, and yet the price is only 5 cts.; 10 for 48 cts.; 100 for $4.50. If wanted by mail, add 2 cts. each extra. The little device is the invention of one of our Medina Co. boys.

TEMPERATURE OF SUB-EARTH VENTILATORS.

SOME INTERESTING EXPERIMENTS.

I HAVE just been making some observations on the temperature of my cellar, sub-earth ventilator, etc., and will give you the result.

Yesterday morning the thermometer stood 14° below zero; and as this was just the temperature outside when C. C. Miller made his tests, it gave me a chance to get at comparative temperatures, and I found my cellar and ventilator just tallied with his; viz., 42° for the cellar, 43° for the air coming in at the sub-earth ventilator. The other end of the ventilator was covered with snow when these tests were made. I wonder if Mr. Miller's was. To-day, in order to know just how much the temperature of the air was raised in passing through under the ground to the cellar, I cleared away the snow at the outside end and put a thermometer in and found it stood 8° above zero, while the general atmosphere was only 4° above, although the bulb of the thermometer was not over 10 inches from the outside. Can it be there is a circulation both ways in an underground ventilator? This would seem to show it, although the inward draft in the cellar is quite strong—so strong that a match burns with difficulty when held in it. Next I again tried the cellar end of the ventilator, and found it stood at 44°, or an increase of 40° degrees over outside temperature. My ventilator, which also serves as a drain, is 80 ft. long and about 8 ft. deep at the cellar end, and comes to the surface at the other end. The opening is made by laying small stones on each side at the bottom of the ditch, so as to leave a space between, and then a flat stone to bridge them over and hold up the dirt. The size of the opening varies, but I think it nowhere less than 2×4 inches.

I consider ventilation of cellars for bees of prime importance, not so much on account of the purifying of the air, as affecting temperature. It is true, that we can keep the temperature up well enough without ventilators; but, can we keep it *down* equally well? Perhaps this might be done with ice; but not every bee-keeper has ice, and I am one of the number who do not believe in a temperature of much over 45° for bees; and if I could have my way about it, I would have it go no lower than 40° nor higher than 50°. How a temperature of 60° can be kept up in this latitude, without artificial means, is more than I can see. Mr. Barber thinks he is master of the wintering problem under his high-temperature plan, because he has saved an average of 80%. I have a record of my losses for 5 years, and the average is a trifle over 16%. I do not think that the advocates of high temperature can claim *all* success for their plan, and I think the idea is fraught with much danger to the novice and inexperienced.

THE TEMPERATURE OF A WELL, AND A SWARM OF BEES IN WINTER.

I have also tested the temperature of my well, which is 123 ft. deep, and find the water, when coming direct from the bottom, is 50°. Do you not suppose that the temperature of water in wells will vary more than the temperature of the earth? To test the heat of a cluster of bees, I pushed the bulb of a common dairy thermometer right down among the bees, put back the quilt, left them until they were quiet, and drew it out. It showed 88°, while the lower end of the cluster hung right out in the air, which was 42°. **C. A. HATCH.**

Ithaca, Wis., Jan. 12, 1886.

AN ARCHED STONE CELLAR, AND THE EFFECT OF A LARGE DRAIN UPON IT 150 YARDS LONG.

Permit me to give you an account of a little experiment, made with reference to the temperature of the earth, etc. I have a cellar, the bottom of which is 12 feet below the surface of the earth. It is covered by an arch of stonework 18 inches thick, with a basement and dwelling-house above it of stone. It is connected with the outside air by 4 flues running from the top of the arch up through and above the top of the house, flues 8 inches square. The cellar has a drain from the bottom, running 150 yards to the lake, from 12 feet below the surface at the cellar, to 4 feet below, where it comes out at the lake. The outlet is two 2-inch tile, but the drain is much larger inside in some places, being of stone.

Jan. 8, thermometer outdoors 14° early in the forenoon, and at 20° when I made the experiment. Temperature of cellar, 45°, six feet above the floor. The wind was coming in at the entrance of the drain sufficiently strong to blow out a candle, and it felt colder than the cellar. I placed the thermometer in the entrance, and was surprised to find it *go up* to 50°. As the air entered the drain at 20°, and was warmed up in its rapid passage to the cellar to 50°, I conclude that the earth at the depth above mentioned must have a temperature greater than 50° here on Pelee Island, Canada.

Jan. 12, thermometer early in the forenoon, zero; at noon, 12° outdoors; 42° in cellar, and 48° in entrance to drain. The cellar is at a low temperature, on account of the flues being open all the time.

THADDEUS SMITH.

Pelee Island, Ont., Can., Jan. 15, 1886.

65° OUTSIDE AND 40° INSIDE.

I am quite interested in the temperature of the earth in different places. In my new bee-cellar, which is six feet deep between floors, the thermometer stands at 40° when it is at 65° outside; and when it goes to 10° below zero outside it goes to 36° above in the cellar, with the sub-earth ventilator open. This ventilator is made so that the entrance for the air is four inches square. It is but 20 ft. long, and is about five feet under ground, nearly all the length of the ventilator. Do you think that 40° is warm enough, or would it be best to use artificial heat to make it warmer? The bees are quiet, and seem to be doing well. **WM. L. KING.**

Sodus, Mich., Jan. 5, 1886.

Reports seem to indicate, as you will notice, that the temperature of the earth varies considerably, even though the depth be about the same. The Mammoth Cave is probably at the highest extreme, but the depth may, of course, have something to do with it. I believe, however, we can depend upon getting a temperature of between 40 and 50 degrees at any season of the year by going down, say, 10 or 15 feet. Am I not right? Landreth, in his catalogue, says that the best temperature for a greenhouse for lettuce, radishes, etc., is between 40 and 50 degrees; and, if I am correct, the general experience of those who winter bees in cellars seems to be in favor of about the same temperature. Some think 55 degrees will do no harm; and for our greenhouses 55 degrees would be very desirable, if we could get it without artificial heat.

THE TEMPERATURE OF MOTHER EARTH.

UNIFORM AT A CERTAIN DEPTH.

FRIEND Allen sends us something which is right to the point we were discussing. It is taken from Ganot's Physics, of 1879, and it reads as follows:

"*Terrestrial Heat.*—Our globe possesses a heat peculiar to it, which is called the *terrestrial heat.* The variations of temperature which occur at the surface gradually penetrate to a certain depth, at which their influence becomes too slight to be sensible. It is hence concluded that the solar heat does not penetrate below a certain internal layer, which is called the *layer of constant temperature:* its depth below the earth's external surface varies, of course, in different parts of the globe; at Paris it is about 30 yards, and the temperature is constant at 11.8° C."

Now, 11.8° Centigrade, if my reduction is correct, is the equivalent of 53.54° Fahrenheit.

I presume, however, that proximity to hidden veins of sub-earth water-ways, and possible volcanic localities, may raise the normal temperature of many tracts of country beneath the ground. Nearness to water, rather than to fire of our burning earth, methinks, most generally modifies the cellars of our friends. FRANK ALLEN.

Philipsburg East, P. Q., Can., Jan. 8, 1886.

Here is another:

52° THE TEMPERATURE OF THE WATER FROM A SIDE-HILL.

You ask for information in regard to the temperature of the earth at considerable depth from the surface. On the 25th of Dec., 1885, I tested the water from a spring gushing out from under a hill some 200 ft. in height, and found the temperature to be 50½° by one thermometer, and 53½° by another. Probably 52° is about the exact temperature for this vicinity. LUTHER PURDY.

Killbuck, Ohio.

You notice from these, that the earth does really have a temperature peculiar to itself, but that the depth at which this is reached varies in different localities. You observe, as a further proof, that at Paris, 53.24 deg. F. tallies closely with that of Mammoth cave, which is 55 deg., with my experiments (97 feet below the surface at our factory), which showed 56 deg., and with friend Purdy's side-hill experiments, which showed 52 deg. It seems to me, then, we do not jump at conclusions when we infer from these facts that the earth has a temperature of its own. ERNEST.

Ernest:—I took my A. I. Root thermometer, tied a string to it, and let it down into my spring. After holding it there some time it registered 46°. The temperature of the air was 34°. The spring is three feet deep, the water coming in from the bottom. I wish you and the "queen" that had spunk enough to swarm out in December much joy, and a long, happy, and useful life. C. K. SCHMELTZER.

Scholl's Ferry, Oregon.

Your experiments differ from those just preceding, because you did not go deep enough. Had you gone, say 100 ft. or more, you would probably have struck the zone of "terrestrial heat," which is 53 deg. Thanks for your kind wishes, and I wish the same joy to you; *i. e.*, if you have a "queen." ERNEST.

Noticing the report of H. R. Boardman and T. H. Kloer on temperature of wells, to-day I tested our well, situated in South Florida, Polk Co., 25 ft. deep. The temperature outside was 39°. I drew a bucket of water, immersed the thermometer, and in three minutes removed it and found it just 70°. If I am here in the summer, I will make the experiment then and find if there is any change.

Lakeland, Fla., Jan. 11, 1886. J. D. COLES.

In your southern clime you would have to go probably much more than 100 ft. to arrive at the zone of "terrestrial heat." Your experiments show that the ground near the surface is much warmer than it is here north. ERNEST.

A PLANER SAW, AND HOW MADE.

REVERSIBLE FRAMES, ETC.

SOME time ago I saw a number of articles on saws cutting smooth. The rip-saw I use for sawing sections is 16 inches in diameter; but the diameter would make no difference. As the Simond's saw-works are located in St. Catherine's, 8 miles from here, I probably am somewhat favored. A year ago I went to the works and asked the foreman if they could concave a saw for me. They replied yes. I gave them my order. The center, or eye, is about one-half as thick as the teeth. I think one less concaved would do as well. It is not quite so rigid on the mandrel as it would be were it not concaved. I can saw smoother than it can be planed. The teeth are about ½ inch apart, but I think ¾ would do as well, and cut faster. One tooth is filed square across back and throat, then the two following are filed right and left on the back; but the throats are all filed square across, or at right angles with the saw. This is done to prevent the teeth from springing outward while at work.

REVERSIBLE FRAMES.

I have never used any yet. Why? Because I never thought they would pay any percentage on the capital and time invested. I should prefer using less frames in the brood-nest with dummies, and, rather than handle the frames so much, even if I did get a slight increase of honey, I should prefer keeping a few more colonies, even if all the honey were stored in sections. I do not want any more feeding, unless I wish increase. Two seasons since, I began bee-keeping. I have fed for increase absolutely. I think if a location will not produce a paying surplus without feeding winter stores, pack your grip and look up a better. Time is worth too much to waste.

8 OR 10 FRAMES, WHICH?

For some time back I have been reading the communications in regard to hives containing eight or ten frames. My opinion is this: That it does not make much difference; but I should prefer a ten-frame hive. When a swarm issues from a ten-frame hive, is it not larger in proportion than an eight-frame swarm? It appears to me that I can see considerable in favor of the ten-frame hive, there being just one fifth more bees to work in the sections. WILL ELLIS.

St. Davids, Ont., Can.

Friend E., we have tried saws concaved in the way you mention; but on account of the greater liability to rattle or shake at the outside diameter, where the teeth are, we finally abandoned them. We get saws to cut just as nicely, I think, made all of a thickness, and the expense is much less.—It seems to me you are hardly qualified to decide in regard to reversible frames until you have used them, and watched the working of them. Those who use the eight-frame hive expect, as a rule, to get as much brood in eight frames as we have ordinarily in ten, obliging the bees to put their surplus honey in the sections. Where a queen occupies ten L. frames, it is almost always true that more or less honey is stored in some of the frames along the top-bar, especially toward the upper outside corners.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 1, 1886.

For where your treasure is, there will your heart be also. Matt. 6:21.

Common nails are ½c. or more lower, per. lb., than the prices given in our price list.

The number of our subscribers this 29th day of January is 4981; 19 more, and we shall be 5000 again.

We take pleasure in calling attention to the advertisement of our good friend Peter Henderson (to be found in this issue), whose name we have so often mentioned as the great pioneer market gardener.

ALSIKE CLOVER.

Until further notice, the price of alsike clover seed will be as follows, instead of according to our price list: Price per pound, 18 cts.; per peck, $2.25; per half bushel, $4.40; per bushel, $8.50; 2 bushels, $16.50.

OUR SEED CATALOGUE.

It is now ready; but, to tell the truth, when compared with the seed catalogues that are sent out by our great seedsmen, ours does not look very handsome. Never mind; we will give you some prices on some things that perhaps will help the matter somewhat.

DISCOUNTS FOR THE MONTH OF FEBRUARY.

Until further notice, we will give the usual discount of 10 per cent on foundation; 5 per cent on sections; and as an inducement for ordering before the great rush comes, an extra 3 per cent on all goods mentioned in our list, ordered during the month of February.

BASSWOOD HENS'-EGGS.

These are not quite as good as the kind they tell about in the papers, that can be told from the genuine egg only by experts, but they are tiptop nest-eggs. They do not freeze, and the old biddies can't eat them up. Price 2 cts. each; 15 cts. for ten, $1.20 per 100, or $10.00 per 1000. If wanted by mail, add one cent each for postage. Supply-dealers who manufacture sections can make bushels and bushels of nice nest-eggs out of refuse bits of white basswood. "Do you see?"

THE SPECIFIC GRAVITY OF MOIST AIR COMPARED WITH DRY AIR.

On page 89, friend C. C. Miller calls attention to the statement on page 43, that moist air is heavier than dry air. Friend Green has got off from the track here; but he is usually so accurate, it was passed unnoticed. Years ago, Prof. Wise, the distinguished æronaut, made a balloon of linen cloth, filled it with common air, and found that, by sprinkling the outside of the balloon with water, the air inside would be dampened to such an extent as to cause the balloon to rise. Warm air will take up a much larger quantity of moisture than cold air. This we notice by seeing the dew precipitated when a body of air is suddenly cooled.

REVERSIBLE HIVES NOT A NEW THING.

If our friends will turn to the *A. B. J.* for June, 1870, they will find an engraving of John M. Price's revolvable and reversible comb hive. The hive is made to reverse not only the brood combs, but the wide frames holding sections as well; and they not only go either side up, but *any* side up, for the frames are perfectly square. Friend Price, at the time the subject was up, urged quite vehemently the advantages of reversible frames, as well as reversible hives, for his hive reverses just as well as each frame reverses. Friend P. is now located in Florida; and with his sixteen years of experience with these reversible frames and reversible hives he ought to be able to give us some favorable suggestions. Can't you do it, friend P.?

SHALL WE FEED OUR BEES SUGAR STORES FOR WINTER?

The statements made by our good friend Wright and Mrs. Harrison may be true; but for all that, if I found by experience that my bees would winter safely on stores of sugar, and would not so winter on honey, I should winter them on sugar, and try to have faith in educating humanity to understand these things as they are. I do not believe my friends and neighbors would conclude I was feeding the bees sugar, and selling it for honey, even if they did see me buying barrels of sugar at a certain season of the year. I believe, however, that the general testimony indicates that stores of good sealed honey are pretty nearly as safe as sugar, and therefore the only advantage in sugar feeding will be when we have got to feed something, and, of course, we may prevent this state of affairs by laying up a reserve stock of combs full of sealed honey; and at the present prices of honey and sugar, I am inclined to think reserved combs are about as cheap feed as we can have, and it is certainly handier than any kind of a feeder. What bee-keeper has not enjoyed having great heavy combs of stores to give any colony that happens to need food? With a hive holding ten frames, unless the colony is remarkably strong in numbers, there ought to be a sufficient surplus in the brood-nest to prevent any such thing as starvation at any time of the year.

THE NEW AGRICULTURE; OR, THE WATERS LED CAPTIVE.

WE have finally made quite a purchase of the above-named book, written by the Honorable A. N. Cole. Of course no one can announce positively on the system laid down in this book until it has had further test in the hands of the average market gardeners and fruit-growers. We extract the two following testimonials in regard to the book. The first is an extract from the report officially made to the Farmers' Club, of Elmira, N. Y., by its President, Mr. James McCann, and ex-President Geo. W. Hoffman:

> The changes wrought in the soil and its products constituted a great surprise. * * * Heavy showers had fallen in the week before our visit, but there was not the slightest appearance of washing. * * * There was a full crop of the most remarkable strawberries, one peculiarity of which was the absence of what may be termed a core or hard stem in the middle; they were juicy and tender all the way through. One plant of older setting had, we should judge, enough berries to fill a hat if they could be picked at one time.

The other was written for the *Husbandman*, of Elmira, N. Y., by the Hon. John H. Selkreg, of Ithaca, N. Y.:

> On the 9th of October, the present month, I looked over and critically examined the garden and field which have been trenched and treated by Mr. Coe. I found strawberry vines which, to me, seemed more luxuriant and thrifty than any which have fallen under my eye at any time. I saw raspberry canes of enormous size, I venture to assert more than one inch in diameter, and of extraordinary freshness and vitality. I saw Champion of England peavines which measured, standing, SEVEN feet from the ground, and containing blossoms, incipient pods, and full-grown peas, in quantity greater than I ever before had knowledge of, and I ate of those peas for dinner that day, and know their unparalleled flavor and delicacy. I measured a pumpkin, in girth five feet four inches; several squashes of about four feet diameter (length); and I helped dig a SINGLE HILL of Early Rose potatoes which, when weighed, tipped the scales at sixteen and one-half pounds, over one quarter of a bushel, five of these potatoes measuring an average of eighteen inches around in length, and nine inches in circumference. Taken as a whole, the wealth of growth upon the land cultivated by Mr. Cole, in my judgment, far exceeds what can be found elsewhere in this or any other State."

The price of the book is $2.00; but we will furnish it to subscribers of GLEANINGS for $1.40; 2 books, $2.50; 10 or more, $1.00 each. If wanted by mail, add 10 cts. each extra for postage.

SHIPPING GOODS WITHOUT CALLING THEM BY THEIR RIGHT NAME.

A CUSTOMER orders a package of honey, but tells us to be sure and not let anybody know the contents of the package; for if his customers found out he was purchasing honey from somewhere else they would jump to the conclusion that it was manufactured, and wouldn't buy. Now, there are very great objections to any such way of doing business. I don't believe it will pay any man, in the end, to mislead his patrons in any way, shape, or manner, either directly or indirectly. The railroad company are at once suspicious of any package where the shipper seems to desire or prefer not to mark on the outside just what the package contains. Of course, they can not tell what classification it should be shipped under, and so, to be on the right side, they will mark it first class, or even double first class. Some time ago the matter was discussed about marking barrels of honey, "syrup," so as to get a low rate of freight. I do not know how a Christian, or even a *simply honest* man, could consistently do any thing of this sort; and after studying the matter over quite a little, I can't see how a Christian, or even an honest man, can very well refuse to tell just what a box or barrel contains when he hands it over to the railroad company. If you can not sell honey and call it by its right name, and tell your customers exactly where you got it, don't undertake to sell any honey except what you raise yourself. May be the above advice may hinder in some degree my selling out that carload that came from California; but I would rather know that my patrons were frank and outspoken in their dealings, than to sell a hundred carloads of honey. The matter of buying sugar in the fall to feed your bees in the winter, comes in here indirectly. I shall always purchase sugar for winter feeding whenever I think it advisable, and I shall do it in broad daylight, without any effort to get any of the barrels out of sight, as if I were ashamed of it. Whenever any inquiry is made, I shall explain the matter as well as I can. If the public don't accept my explanation, I shall try to bear it.

CATALOGUES RECEIVED FOR 1886.

The friends will please put a date on their circulars when they are having them printed; for if they don't, how else are we to tell whether it is the same circular we noticed last year, or the year before, or a new one?

J. A. Humason, Vienna, O., sends a 4 page circular; specialty, chaff hives; also Italian bees.

J. B. Mason & Son, Mechanic Falls, Me., send us a little pamphlet of 50 pages, containing much valuable matter, besides prices on almost every thing pertaining to the bee-business.

Joseph Nysewander, Des Moines, Ia., sends us a catalogue of 48 pages, supplies in general.

Wm. Groff, Rome, N. Y., sends a 4-page circular. His specialty is Groff's Common-Sense bee-hive. May we suggest to friend G., that the term "Common-Sense," as applied to bee hives is in rather bad favor? It was especially so five or six years ago, as he will see by our back volumes.

Hughes & Tatman, North Topeka, Kan., send us their circular specialties, Plymouth Rock and Light Brahma fowls; also bees and queens.

Kennedy & Leahy, Higginsville, Mo., sends us their price list of last year, with change of prices on the cover.

J. T. Fletcher, Clarion, Pa. Specialty, fowls; also bees and queens.

C. W. Costellow, Waterboro, Me., 12 page price list; general supplies.

James Heddon, Dowagiac, Mich., sends us a 26-page circular; specialty, Heddon's new hive. This circular contains considerable matter of interest to bee-keepers, aside from the goods friend H. offers for sale.

J. V. Caldwell & Co., Cambridge, Ill., send a 16-page catalogue; specialty, Given foundation-press.

E. T. Lewis & Co., Toledo, O., send us a 32-page catalogue, very comprehensive, fully illustrated.

Among the catalogues lately printed at this office we notice the following:

A 12-page price list for J. W. Bittenbender, Knoxville, Ia.; supplies generally.

A 12-page list for for F. Boomhower, Gallupville, N. Y.; specialty, Italian bees and queens, and English rabbits.

A 6-page list for John Nebel & Son, High Hill, Mo.; bees, queens, fdn., etc.

A 4-page list for B. V. Hubbard & Co., Temple, Texas; hives, and supplies in general.

CONVENTION NOTICES.

The annual convention of the R. I. Bee-keepers' Society will be held February 11, 1886, in Providence. GEO. A. STOCKWELL, Sec.

Providence, R. I., Jan. 27, 1886.

The Seventeenth Annual Convention of the New York State Bee-Keepers' Association (formerly North-Eastern) will be held in Rochester, N. Y., on 17th, 18th, and 19th of Feb., 1886.

Perry Center, N. Y. F. C. BENEDICT, Sec.

AN OMISSION AT THE DETROIT CONVENTION.

The report of the committee on exhibits at the recent convention of the N. A. B. K. A. at Detroit did not include the exhibit of G. B. Lewis & Co., of Watertown, Wis. They call attention to the omission, and say, "Our sections were displayed in the sample room of the Newhall House, and also they were brought down to the office." This accounts for the omission in the report, for the committee supposed that all the exhibits were made at the Antisdel House. They also say, "We exhibited only 4¼x4¼ open-top, very white, basswood sections, and some English section-folders."

Toledo, O., Jan. 22, 1886. A. B. MASON.

STANLEY'S

AUTOMATIC HONEY-EXTRACTOR

Is acknowledged by all practical bee-keepers to be the most perfect and complete honey-extractor known. The weight of the combs reverses them the instant the motion stops, and they never miss. The Automatic is highly recommended by the following prominent bee-keepers:

Ira Barber, Prof. A. J. Cook, W. E. Clark, H. D. Cutting, F. F. Crooker, C. P. Dadant, W. T. Falconer, James Heddon, C. R. Isham, D. A. Jones, Dr. A. B. Mason, J. H. Martin, A. E. Manum, S. T. Pettit, A. I. Root, L. C. Root, J. H. Robertson, I. L. Scofield, F. A. Salisbury, J. M. Shuck, T. L. Von Dorn, and a host of others.

On account of the great call for our machines throughout the West and South-west we have decided to start another factory to accommodate that trade, and for that purpose J. E. Stanley has located at Topeka, Kansas, where he will manufacture the Automatic honey-extractor and dollar smoker, and where he will, in connection with Stanley Bros. there, establish a honey-store. Stanley Bros. are extensive wholesale dealers in fruits, nuts, and confectionery, and have a large trade through Kansas, Nebraska, and Colorado. J. E. Stanley is a practical honey-man, and will have full charge of the honey department.

All orders for extractors west of the Mississippi River (except from California), and also Wisconsin, Illinois, Kentucky, Tennessee, Mississippi, and Alabama, should go to the Western house. Orders for all other States east of the Mississippi River, as well as from all foreign countries, should come to the Eastern house.

Californians wanting our machines should apply to Messrs. Baker & Barnard, of San Buenaventura, Ventura Co., Cal. These parties order the reels from us, and make machines to order. This will be a great saving of freight to purchasers.

Our prices for machines taking the L. frame are as follows:

2-frame machines, without gear............	$12 00
3 " " " "	16 00
4 " " " "	21 00
6 " " " "	30 00

The above prices are for our machines without gear, but with crank attached to top of center-shaft. We add a strong vertical gear, with crank at side of can, for $2.00 extra, or a horizontal gear for $1.00 extra. If any frame, except the standard L., 9⅛x17⅝, is used, please mail us a sample frame and get prices on the machine you want.

Always address the house in your own territory.

J. E. STANLEY, Topeka, Kansas. **G. W. STANLEY,** Wyoming, N. Y.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error.

WANTED.—To exchange new Novice honey-extractors for A. and L. frames; will exchange for a bone-grinder, or good books, or any thing useful. GEO. W. BAKER, Milton, Ind. 3-5 7-9-11-13d

WANTED.—To exchange one-half bushel of extra fine white-clover seed for alsike-clover seed. 19tfdb M. A. GILL, Viola, Richl'd Co., Wis.

WANTED.—To exchange or sell. Friends, I have 15 pairs of the celebrated Bonney's stock of Brown Leghorns that I will sell at $3.00 per pair, or will exchange for good beeswax at 25 cts. per pound. Circulars free. Ref., A. I. Root.
24tfdb A. H. DUFF, Creighton, Guern. Co., O.

WANTED.—To exchange golden-willow cuttings for Italian queens. I will book orders now, and send the willows as early as will do next spring: queens wanted in May and June, 1886. 2 dozen cuttings for a warranted, and 4 dozen for a tested; also one weeping-willow cut with each dozen. Will send by mail. S. C. FREDERICK,
24, 5db Coal Vale, Craw. Co., Kan.

WANTED.—To exchange a buzz and scroll saw combined, one polyoptican, new, one Smith American cabinet organ (catalogue price $210.00), all in perfect condition, for Plymouth Rocks, Chester or Poland pigs, Holstein or Jersey calves, or young cattle. L. W. LIGHTY,
2tfdb Mulberry, York Co., Pa.

WANTED.—To exchange strawberry and raspberry plants for $1.00 or tested queens, or pounds of bees (in spring). Address 2 tfdb
C. W. PHELPS & Co., Tioga Centre, Tioga Co., N. Y.

WANTED.—To exchange choice grapevines (5c each), fdn. machine, and hand printing-press, for buckwheat, beeswax, etc. Write to
3d F. C. MORROW, Wallaceburg, Ark.

WANTED.—To exchange two handsome cases of stuffed birds, for bees, comb fdn., or ex. honey; also eggs of P. Rocks and Brown Leghorns, $1.50 per sitting, for bees, queens, or comb fdn. mill.
Address T. G. ASHMEAD, Williamson,
3d Wayne Co., N. Y.

WANTED.—To exchange for a farm, or sell my place, consisting of 7½ acres of ground in the town of Lewisville, Ind. A small dwelling, poultry-houses, stable, and an everlasting gravel-bank, which affords about 3000 loads of gravel every year, which sells readily at from 10 to 15 cts. per load. The place is in a good honey locality, and good shipping facilities. Apiary slopes to the south and east; is surrounded on the north and west by a tight plank fence, about 7 ft. high. Apiary is set in grapevines. I will give five years' time, if sold. Direct all communications to
3-5-7d GEO. W. BAKER, Milton, Ind.

WANTED.—To exchange Simplicity hives for a circular-saw mandrel for hive-making by steam power. Will sell hives (in the flat) cheap for cash, or will take one-third pay in full colonies of bees. Hives in any quantity to suit customers, up to a carload per day. G. A. FARRAND,
3tfdb Rockport, Cuyahoga Co., O.

JOB LOT OF WIRE CLOTH
AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

Inches Wide.	No. of Rolls.	SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED. This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc. Number of Square Feet contained in each Roll Respectively.
10	1	1 roll of 72 s. f.
20	3	3 rolls of 166 s. f. each
22	1	1 roll of 160 s. f.
24	3	3 rolls of 200 s. f.
26	71	22 rolls of 217, 38 of 216, 2 of 195, 1 of 156, 2 of 215, 1 of 210 s. f.
28	13	11 rolls of 233, and 2 of 234, s. f.
34	7	5 rolls of 281 s f.
38	37	28 rolls of 316, 3 of 285, 2 of 317, 1 each of 190, 632, 126, and 215 s. f.
42	1	1 roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
46	1	1 roll of 152 s f.
48	4	4 rolls of 400 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
20	1 roll of 155 s. f.
22	1 roll each of 88, 143, 92 s. f.
24	43 rolls of 200 sq. ft. each; 1 each of 95, 120, 168, 190, 10, 150 140 sq. ft.
26	57 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 54, 204 sq. ft.
28	73 rolls of 233, 11 of 224, 3 of 229, 8 of 222, sq. ft.; 1 each of [illegible], 245, 257, 93 sq. ft.
30	36 rolls of 250 sq. ft.; 1 each of 137, 225, 125, 125, 220, 227, 237, 235, 275, 240 sq. ft.
32	13 of 266, 7 of 256, 2 of 253 sq. ft.; 1 each of 233, 250, 275 sq. ft
34	30 rolls of 283 sq. ft. each.
36	22 rolls of 300 sq. ft. each; 1 each of 288, 150, 279, 285, and [illegible] sq. ft.
38	1 roll each of 309 and 316 sq. ft.
40	1 roll of 233 square feet.
42	1 roll of 350 square feet.
46	1 roll of 192 square feet.

A. I. ROOT, Medina, Ohio.

3-6db S. SMITH, New Smyrna, Volusia Co., Fla.

GOLDEN-WILLOW CUTTINGS, for one cent each postpaid. Two-cent stamps preferred.
3d S. HEATH, Rimer, Armstrong Co., Pa.

KIND WORDS FROM OUR CUSTOMERS.

THE BEE-PAPER.

If there is any other paper that I have not yet heard of that is equal to GLEANINGS, put my name down. I have four bee-journals, and GLEANINGS is, I think, *the* bee-paper. H. E. HILL.
Titusville, Pa., Dec. 17, 1885.

OUR CALIFORNIA HONEY.

I received the can of honey all right, and am very much pleased with it. I think it is as nice honey as I ever saw or tasted. I shall want some more of it after awhile. C. E. JONES.
Delaware, Ohio.

The two cans of California honey shipped Dec. 19th arrived here on the 30th in first-class condition. The honey has been declared by several persons as the finest they ever saw or tasted. I think it will sell rapidly. 3—GUSTAVUS WIEDERHOLD, 5—7.
Yonkers, N. Y., Jan. 1, 1886.

THE BEE-KEEPER'S WHEELBARROW.

The goods came all right. The wheelbarrow is the most complete, I think, I ever saw. Oliver, 8 years old, can wheel 50 lbs. on it with ease. The bees are doing finely, with good stores and a fly every few days. C. F. UHL.
Millersburg, Ohio, January 1, 1886.

WHAT G. M. DOOLITTLE THINKS OF GLEANINGS.

GLEANINGS for Dec. 15 has come to hand, the wrapper telling me that you make me a present of it for 1886. Very many thanks indeed. I wish to say that GLEANINGS is gaining ground; i. e., growing better and better every year.
G. M. DOOLITTLE.
Borodino, N. Y., Dec. 22, 1885.

A KIND WORD FOR THE SECTIONS WE ARE MAKING THIS YEAR.

The sections are just a little bit the nicest I have ever had. I have bought all my sections for the last 7 years, and these are the first that have altogether filled my idea as to what they ought to be. Although I have never complained to dealers, I have always thought they might be a little more careful about dovetailing the ends so they would not leave a jog of a 1-16 or ⅛ when driven together. These are just right. The counter goods are fully worth the money. Please accept thanks.
Summersville, Pa., Jan. 20, 1886. J. A. CLARK.

3tfdb Rockport, Cuyahoga Co., O.

HONEY COLUMN.

CITY MARKETS.

KANSAS CITY.—*Honey.*—This market continues about unchanged, except that stocks are somewhat reduced, and, possibly, a little firmer feeling on extracted. The demand, however, is not heavy for this time of the year, and we can't expect any better prices, as no one seems inclined to hold, and concessions all in buyer's favor. Choice 1-lb. sections were best at 15@16c; 2-lb., 13@14c. Extracted, 5@7c, according to quantity. *Beeswax* is in very light supply; would bring 22@25c for good average grades.

CLEMONS, CLOON & CO.,
Cor. 4th & Walnut St's., Kansas City, Mo.
Feb. 6, 1886.

NEW YORK.—*Honey.*—We note an improvement in sales of honey the past week, but prices continue to rule low. We quote as follows:

Fancy white comb, 1-lb. paper cartons,	13@14c.
“ “ “ “ glassed or unglassed,	12@13c.
“ “ “ 2-lb. glassed,	9@10½c.
Fair to good “ “ glassed,	8@9c.
Fancy buckwheat, 1-lb. unglassed,	10c.
“ “ 2-lb. glassed,	8@9c.
Extracted, white clover, per lb.,	6½@7½c.
“ Buckwheat “ “	5@6c.
Beeswax,	28@28c.

MCCAUL & HILDRETH BROS.,
Feb. 10, 1886. 34 Hudson St., cor. Duane St.,
New York.

CINCINNATI.—*Honey.*—Demand for extracted honey is extremely slow. Manufacturers, apparently, are taking a rest. There is only a fair demand for honey in glass jars and for comb honey. Prices are unchanged and nominal, with occasional arrivals, and a large stock on the market. We quote extracted honey at 4@8c on arrival, and choice comb honey at 12@14c in the jobbing way. There is a good home demand for beeswax. We pay 25c per lb. on arrival.

CHAS. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
Feb. 2, 1886. Cincinnati, Ohio.

NEW YORK.—*Honey.*—There is a slight improvement in the honey market. We have had a fair demand for comb honey, and a very good demand for extracted honey for the past two weeks. The indications are that there will be a good demand for honey during February, March, and April, especially for the finer grades. We make no changes in our quotations from our last issue.

THURBER, WHYLAND & CO.,
Feb. 11, 1886. Reade & Hudson Sts., New York.

BOSTON.—*Honey.*—The sale for honey for the past month has been as light as we ever knew, and prices are weak. One-pound, white clover, 13@15: two pounds, 11@13; extracted, 6@8.

BLAKE & RIPLEY,
Feb. 11, 1886. 57 Chatham St., Boston, Mass.

CLEVELAND.—*Honey.*—There seems to be quite a little activity in our market now for choice 1-lb. sections, which sell at 14@15c; 2 lbs., not very active at 13@14c. Old honey, of which there is some still on hand, is very slow at 10@11c. Extracted, 7@8c. *Beeswax*, very scarce at 25c.

A. C. KENDEL.
Feb. 11, 1886. 115 Ontario St., Cleveland, Ohio.

CHICAGO.—*Honey.*—Market without special change from last quotations; choice comb honey in ¾ to 1-lb. sections is wanted in this market when put up in desirable shape.

R. A. BURNETT,
Feb. 10, 1886. 161 So. Water St., Chicago, Ill.

DETROIT.—*Honey.*—Was in the city yesterday and looked over the commission houses. Find honey dull. Best white in 1-lb. sections, 14c; larger sections a little less. *Beeswax*, 23@25c.

Bell Branch, Mich, Feb. 11, 1886. M. H. HUNT.

ST. LOUIS.—*Honey.*—The honey trade is slow. Comb, such as is on the market, is selling mainly at 12½c. Extracted, quotable at 8@10c. in cans, and 4½ to better for bbls., as to quality.

Beeswax.—We quote at 23c; demand good.

Feb. 11, 1885. W. T. ANDERSON & CO.,
104 N. 3d Street, St. Louis, Mo.

FOR SALE, very cheap.—Six barrels white-clover, extracted honey, and four barrels fall extracted honey (Spanish needle and goldenrod). Samples sent on receipt of three 1-cent stamps for each sample. EMIL J. BAXTER, Nauvoo, Ill.

HONEY AND BEESWAX.

We are now in the market, and will be during the entire season, for all honey offered us, in any quantity, shape, or condition, just so it is pure. We will sell on commission, charging 5 per cent; or if a sample is sent us, we will make the best cash offer the general market will afford. We will handle beeswax the same way, and can furnish bee-men in quantities, crude or refined, at lowest market prices. Our junior member in this deparment, Mr. Jerome Twichell, has full charge, which insures prompt and careful attention in all its details.

Sample of comb honey must be a full case, representing a fair average of the lot. On such sample we will make prompt returns, whether we buy or not.

THE NERVOUS SYSTEM OF THE BEE.

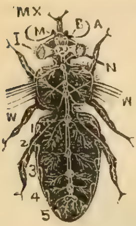
NERVES IN GENERAL, AND THEIR RELATION TO PAIN.

BEFORE entering upon the subject at the head of this article, let us briefly examine the nervous system of the human body, and discover, if possible, what is the function of the nerves; that is, what are painful and pleasant sensations—their origin and relation to motion. We can then better understand the nervous system of the bee.

Our bodies are provided with a great mass of nerves, of which the spinal cord, located in the backbone, and the brain, are the source from which these nerves branch out, and to which the nerves communicate all sensation. The whole structure is in form like a tree, the trunk of which is the spinal cord. From this are nerves, branching and rebranching throughout the whole body, until they become so small as to be microscopic in size, and so numerous that even the point of a pin, on coming in contact with the flesh, will communicate sensation to one or more of these nerves. As the nerves are more thickly crowded near the surface of the flesh, the surgical knife gives more pain while passing the skin than when it has penetrated further. Without these nerves we could feel no pain nor enjoy any pleasant sensation, as to see, feel, hear, or taste.

WHAT IS PAIN?

Pleasant sensation and pain are akin to each other, but different in degree. For instance, a warm fire is agreeable to cold hands; but if we should place those hands in the fire, we should undergo great agony. A certain amount of light is pleasant to the eyes; but direct sunlight gives pain. Now, the higher the intellect, and the higher the scale of creation in general, the more complicated the nerves, and, in consequence, the greater the power to enjoy pleasant sensation, and to experience pain. The lower the scale of development, and the simpler the structure, the converse is true. Hence man, of all creation, can experience the highest degree of pain or pleasure. On the contrary, the earthworm, when cut in two, by reason of its simpler structure feels comparatively little pain. True, it wriggles; but, so far as I know, the two parts perform the same function as before. You may cut a water-hydra (one of the simplest forms of animal life) into several pieces, and yet each will become as perfect as the parent. Then we infer that, accordingly, as the bee is simpler in general structure, and likewise in its nervous system inferior to that of man, so much less pain does it feel at the bungling hands of the apiarist. It certainly is a very wise provision of our Creator, in so constructing the lower forms of life that the latter, as a prey to the higher forms, may not undergo the agony that we would feel were we to be devoured by some terrible monster. The birds subsist upon insects and worms of all kinds, and God has so ordered it that these lower forms should not suffer, in proportion as we do. How do we know the lower forms of life feel less pain? Because microscopic examination shows their nervous system to be simpler as we proceed down the scale of animal life. The lowest class of animal life of which we have any knowledge, as the *Protozoa*, have no nervous system whatever, and are incapable of receiving any sensation, unless it be contact with other bodies. In fact, we find no nervous system until we come to the sub-kingdom of *Annuloida.*



Some one has said, that the bee is to the insect what the horse is to the animal. If we look at the cut opposite (after Cheshire), we shall see that the nervous system of the bee (represented by the white lines), though complete for the bee, is by no means as perfect as in that in the human body. As it would take a physician to point out the exact difference and marks of inferiority, I will not enter into full particulars here. The two medial and parallel lines traversing the whole length of the bee are what corresponds to the spinal column, though not the same in structure. Along its course, and intersecting at irregular intervals, are little disks with a white spot in the center of each. These are nerve centers, or, as they are termed, ganglia. From each of these ganglia, as you will notice, is a branch of nerves, some of which extend along the legs of the insect. As in the bee, we have something in our bodies corresponding to these nerve centers, or ganglia. They preside over the involuntary muscles, as respiration, digestion, pulsations of the heart, etc. It will be observed that they relieve the brain of a large amount of work. If the brain had to preside over the hidden machinery of our bodies, besides controlling our mind and actions with reference to the outside world, it would be like a man with too many irons in the fire. We should forget to breathe, or to make the heart beat, while performing some of the difficult problems of life.

Returning to the cut, if we touch the foot of a bee the sensation travels up the leg, as it were by electricity, until it reaches its ganglion. The impression, according to Cheshire, takes several courses, some communicating with the brain, and others transmitting the impulse to the other legs. The effect is almost instantaneous, and the legs (if the bee is held by the wings) will set up a vigorous kicking. To illustrate further the difference between the ganglia and the brain, as before stated, let us cut off the head of a bee, and note the effect. The brain, represented by the little lobes between the eyes in the cut, is now completely separated from the body of the bee, and yet the wriggling goes on as before, and will continue to do so for five or six hours or more. With the tweezers we grasp one of the legs. The other legs will come to the rescue, and struggle vigorously to push off the offending object. The sting, too, makes a desperate attempt to thrust out its fangs. In, fact, the headless victim seems to be so far in possession of his faculties as to be actually alive. A mud-turtle, as I have found by repeated experiment, will crawl about, a week or more after his head has been completely shot off. Do the bee and the mud-turtle live, and do they feel pain after decapitation? Facts seem to indicate that they do not, and that these singular movements are only manifestations of the nervous ganglia. In lower animals, these nervous centers seem to be possessed of more functions than those of our body. If a man is beheaded, all outward movements of the body are suspended almost immediately; but not so with the bee. In removing the head of a bee, the power of motion and the seat of consciousness are completely separated, and the line of communication between the nervous ganglia and the brain has been broken. How do we know that, therefore, a bee does not suffer pain? By analogy, and experiments upon the human family. Well-authenticated cases are related in medical works, of soldiers in battle being shot in the backbone, thereby completely severing the spinal column. Below the wound, paralyzation sets in throughout that part of the body. If the feet be now tickled or pinched, they will jerk back violently; but the wounded soldier has no knowledge of these movements, except as he sees with his own eyes what is transpiring. After the spinal cord is united, sensation returns to the affected parts. The spinal cord in the neck of a frog may be severed, and the phenomena will be almost identical with the case just mentioned. From these, you observe that direct communication must be established with the brain, in order that pain from bodily injury may be felt.

The physician gives cloroform and ether, either to paralyze the nerve centers, or to render the patient unconscious. In both cases he will feel no pain while the operation is going on. So with the bee. The seat of consciousness is removed, when the head is cut off. He may wriggle for hours, and yet feel no pain. Like the mud-turtle, when his head has been cut off, as the boy said, "He is dead and don't know it." Ernest R. Root.

BEE-TALK.

HOW WE DO OUR EXTRACTING.

We usually keep from 50 to 60 colonies in an apiary, spring count, and we think that number about right. That gives us a fair day's work for our crew of boys, after going from four to nine miles with teams to get there, and gives us time to go home and pack our honey in barrels, and we think, to get the best returns in honey, that number is large enough. As we live in the borders of a town of 4000 inhabitants, there are plenty of boys whom we can hire, as many of them have nothing to do, and are glad to get a job. We hire them from 12 to 20 years old. Beginning with the 12-year-old boy, we pay him the first year $6.00 or $8.00 a month. That depends on what kind of a boy he is. We hire for the lowest figure, and give him more if he earns it. The next year, if the boy has been faithful, we hire him again, and give him about $2.00 more a month, and about one month in a year is as long as we have use for the most of the boys. As we have 11 acres of land to cultivate, some of it in small fruit, we hire one or two of our best boys in the spring, about April 1st, and keep them all the season. We commence to extract about the 15th to the 20th of June. Then we take in two more young boys; and when we have gone over all the bees once, we put on our whole force.

The last two years, including myself and my son, our force has been ten hands, besides one carpenter at work in the shop at home. I have no doubt but some of the bee-masters will laugh at the amount of help we employ to do our work. But, recollect we spend from 1½ to 3 hours on the road, going to our work every morning, and as much coming home again; go with two teams, one to carry the boys and the other to haul the honey and traps we have to take along, and we think we are working to the best advantage. Perhaps we are not.

We have our apiaries laid out in rows, so arranged that we have what we call Main Street running through the center, about 20 feet wide, for a wagon-road. Just about the center of the yard, and by the side of Main Street, we locate our extracting-house, which is a temporary affair. We set 4 posts in the corners, just 10 feet apart outside measure, and 8 feet high above the ground. Around the bottom we nail boards 12 inches wide. Around the top we nail on another round of 12-inch boards, so now we have a 6-foot space with no siding on it. For siding we take two breadths of cheese-cloth, 40 feet long, and sew them together side by side, making a piece 6 feet wide and 40 feet long. This will just reach around our house. About one foot apart, all along the edge of this cloth, we sew on strips of leather, about one inch wide and 6 or 8 inches long (we cut them from old boot-legs), leaving the leather clear of the cloth about 2 inches. To put on the siding, we commence at one corner, nail through the leather strips to the corner post one end of the siding; now nail all along the top edge of the cloth through the leathers, to the bottom of the top round of boards; go clear around the house, except the last 3 feet; there we have a wire-screen door, with spring to shut it; or, in the absence of the wire screen to cover the door, we nail our siding to the top of the door. As it is 40 feet long, and the house 10 feet square, it will just reach. Now fasten the bottom edge to the bottom board the same way, and we have a siding bee-tight, if we keep the door shut.

For the roof we have a cloth cover 10 feet square, with leathers sewed on the edges the same as the siding, which is nailed to the top round of boards, and held up in the middle by two pieces of 2×4 scantling, just long enough to reach across the top from one board to the other. The framework of the house is made just alike in each yard, and, of course, stays there; but the siding and top cover we take with us and put it up every day. We can put on the top and siding in five minutes, and take it off quicker. We are going to improve the roofing of our extracting-house. Sometimes a shower will come up suddenly, when we are at work, and our thin cloth roof, put on flat, doesn't shed water. We are going to make a top cover of duck, and put it over a ridge-pole, elevate the ridge two feet above the eaves, draw the cloth tight, and, as there will be no bearings from the ridge to the eaves, it will shed water. Now we have our house, and are ready for work.

We have an extractor for each of our apiaries, and keep them there during the honey season. We have kegs that hold 160 lbs. of honey each. We take as many of them with us as we expect to fill. Be sure to take enough, as it is easier to take back an empty keg than it is to bother with an overplus of honey. We use one keg for a strainer-keg, having a good-sized faucet near the bottom, to draw out the honey. We tie a square yard of cheese-cloth over the open end of the keg, and let it sag into the keg enough to hold a large pail of honey. In the corner of the house, handy to the extractor, we dig a round hole, one foot deep, large enough to set in one of our honey-kegs to be filled; close by the side of the hole we set another honey-keg; on that we set our strainer-keg, with faucet over the keg, in the hole, which has a tunnel in it, and in the tunnel a wire-screen strainer to catch any stray bees that may be liable to get into the honey in passing from the strainer keg to the store keg below. When one keg is filled we roll it out and put under another. We set our extractor about the middle of the house, fronting the door. As the combs come in from the field or hives, they are placed just by the right-hand side of the door. Now, half way from the door to the extractor we place a honey-keg on end, and on that we place our cap-catcher. We use a wooden keeler, holding about a large pailful. Two hands work in the house—one experienced hand, and a boy. The boy stands by the uncapping-stand, takes up a comb from where they are set when they come in from the hives, uncaps it, and sets it down, leaning it against his stand, on the left side, between him and the extractor. That is his work—uncapping combs, and he doesn't have any time for fooling. The man at the extractor picks up the combs at his right hand, extracts them, and sets them down by the left side of the door, empty, ready to go back to the hives. The combs have made just a half-circle since they came into the house, and are now just by the side of the door, where the outside boys can reach in and get them, without going in and getting in the way. We have a large tin pail made for the purpose, that sits under the extractor, in which to draw the honey and pour into the strainer-keg, which stands in the corner, at the left of the man who runs the extractor; and it is his part to extract and fill the kegs, and look after his boy and keep things in order in the house.

Now, as we worked ten hands last year and the year before, there are eight at work among the bees. Take one of the most experienced hands, and give him two boys to help him; then make up another trio of boys the same way. Three hands make a good set to work together. After making up the two sets there are two hands left, and that is usually myself and the greenest boy in the lot. Now, one set of hands takes with them a smoker, and each a brush to sweep bees from the combs, and what we call a swarming-box. It has a bottom and three sides, leaving one side open. Set that down by the side of the hive to be worked; give the bees a little smoke; turn back the cover and pry up the honey-board, take out the movable front and front cushion. Now our frames are standing on the bottom, flatwise to us. Just take a glance to see if the queen is in sight; if not, take out the first frame, and set it into the swarming-box, with the back side of the comb toward the open side of the box. We want to find the queen, and we have parted two combs, so there are two places to look. Let the foreman who takes out the combs look in the hive, and his assistant look in the swarming-box. If she is not seen, then take out another comb, and look until all are out; and then if the queen has not been seen, look over the few bees that remain in the hive. Sometimes she will be found there. If she is found we put her in a cage until we are done with the hive, and then let her out into her own hive. It is very seldom that we miss finding the queen when we are taking the combs out of the hive. If we should fail to find her we look carefully when we sweep the combs, when she will usually be found. If we fail to find her at all, we don't take any of the bees to make up new colonies.

Well, when we have the combs out of the hive we sweep the bees all off, into the hive, and send the combs to the extracting-house by the small boy. The first hive we open we leave without combs until we get through, and then fill it up with the combs of the last hive opened, so that no colony gets its own combs back again. Now, after each set of hands has a hive shut up without combs, and the combs are all in the house together, then each set opens another hive, finds the queen, cages her, and then the foreman and one of his assistants take a comb by the corners and sweep each one side of the comb—brushing the bees either into the hive or swarming-box. When they have four or five combs clear of bees, the other boy takes them, two or three in each hand, and carries them to the house, and brings back as many empty combs and sets them into the hive. By that time the rest of the combs are ready to go to the house. When the boy takes them and brings back enough to fill out his hive, he fills up the hive and liberates the queen, and then shuts up the hive. By the time he gets his hive done, the other two boys have some combs from another hive, ready to go to the house, and so we go, some taking out combs and sweeping off bees, others going and coming with combs, and shutting up, others extracting and putting up honey, all as busy as bees, while the boss does what he can and oversees the whole yard. We take our dinner and supper with us, and have a picnic every day. When we get done we down with our tent, load up, and then hitch up and drive home, and then draw our honey out of the kegs into barrels in the honey-house, and mark the date of the year and day of the month on each barrel; also mark × for the first extracting, ×× for the second, and ××× for the third, etc.

During the extracting season we have very busy times. If we lose a day, from any cause, it just means a loss of 1000 to 1500 lbs. of honey. The most we ever took out in one day was the 20th of July, 1885, when seven of the boys, including my son, went four miles and took 2075 lbs., and I had two boys to help me in the home yard, and we took 880 lbs. the same day, making 2956 lbs. of basswood honey. There were 15 days that we took 1000 lbs. and over each day, in the season of 1885.

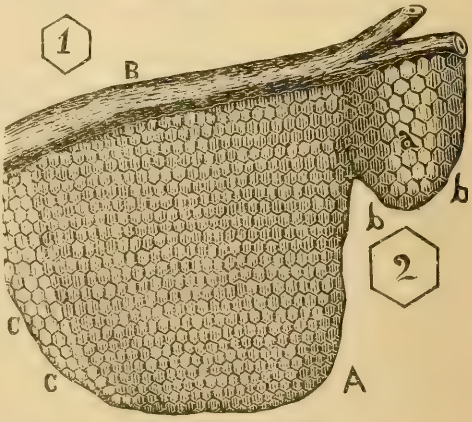
Platteville, Wis. E. FRANCE.

Why, friend France, you almost take away one's breath. I do not know that we have before had an account of where extracting is done with such system as you manage it; and, best of all, instead of advertising for experienced help, you take boys right around your own home—common, every-day boys, such as all of us find everywhere. These boys enjoy the work, of course they do. It is a "picnic" to them, as you say, and yet they earn money, and learn industry and thrift. The education you give them is, without doubt, worth more than the money they receive, and you are helping to solve this vast problem of finding something to do for a world full of uneasy and discontented people. I can easily understand how every thing goes along like clockwork, when the bees are not disposed to rob; but let a dearth of honey come, when the hives are full, and, oh my! what a time! But very likely you keep so well up with your work, that, when the dearth comes, you are ready to stop. I know you have had some experience with robbers, from the precautions you take; and if such precautions are not taken, the bees often get to robbing when there is *not* a dearth. Now, friend F., you have given us a glimpse of your busy home, and we want to know more. How do you sell all this honey? What do you do when swarming time comes? How much increase do you make? Tell us more about it. With ten men and boys to look after, I can readily imagine you have all you want to do, without working very much yourself, and I shouldn't wonder if you would have abundant need of that "greenest boy" to run errands for you. It reminds me a good deal of the way we often manage here on our own grounds.

SOMETHING MORE ABOUT THE APIS DORSATA.

HOW THE COMB IS BUILT; SIZE AND DEPTH OF CELLS, ETC.

FRIEND ROOT:—Herewith I send a drawing of *Apis dorsata* comb. I hope it will make my description clear. I shall try again this year, if I can get time, to investigate this bee. I wish you could be with me here a month or so this cold season. I would show you all the bees of the country, and, best of all, I would show you 81 churches, nearly 2500 baptized adult members, with schools, etc., that you might rejoice with me in the ability of God's word, in the hands of the Holy Spirit, to lift the lowest.



APIS-DORSATA COMB.

A is the brood comb, which is of a pale amber color. Cells here are beautifully regular, and comb perfectly straight. See measurements formerly given. B, is a limb of a tree. C, new brood-comb, and enlarged in direction of C C; *a*, honey-chattie, spherical in shape. Deepest honey-cells are at *a*, and three to the inch; *b*, shallowest honey-cells. Honey-cells are so arranged in honey-chattie, as regards length, as to form a cylindrical shape on the limb. No brood is ever placed in "honey-chattie." It contains pure white, or pale amber honey, and the comb for honey is beautifully white.

Toungoo, British Burmah. A. BUNKER.

For an explanation to the above cut, our friends are referred to page 342 of our issue for May 15, 1885. You will find there that I could not quite understand friend Bunker's description of the peculiar comb which the bees build, expressly to store honey in. This comb is named, as you will notice above, "honey-chattie." The large comb occupying the central part of the engraving is the single brood-comb attached to the limb. By referring to the former article mentioned above, we find that this honey-chattie is sometimes as much as six inches in thickness, making the cells on each side three inches in depth, properly sloped to prevent the honey from running out. Fig. 1 gives the size of the cells for the brood-comb, being about like our drone-comb. Fig. 2 shows the size of cells of this strange honey-chattie. By the way, friends, wouldn't it be a curiosity indeed, if it were possible to get one of these great chunks of honey across the ocean, to be shown at some of our national conventions? What a crowd it would bring! Friend B., don't you think it possible? We are anxiously awaiting the result of your experiments in trying to domesticate *Apis dorsata*.

THE TEMPERATURE OF THE EARTH.

SOME VALUABLE FACTS, FURNISHED BY FRIEND S. CORNEIL.

In view of recent references to the temperature of the earth, the following facts may be of interest to the readers of GLEANINGS. As regards temperature, the crust of the earth, down to the point where the internal heat is met with, may be divided into three strata. In temperate climates, the limit of the first stratum is reached when the thermometer ceases to indicate the diurnal changes of temperature at the surface. This is at a depth of three to five feet, depending to some extent upon the nature of the soil. From this point down to 40 ft., and in some cases to 100 or 120 ft., according as the material passed through is solid rock, clay, sand, or water, there is a stratum, the temperature of which is affected by the changes in temperature of the seasons only. Below this there is a stratum having a constant temperature, but whose degree of heat depends upon the mean annual temperature of the locality. After this stratum, having an "invariable temperature," is passed, the temperature of the earth increases 1° for every 50 to 75 ft. in depth. The following quotations from authorities on the subject will perhaps be appreciated by the reader:

> In temperate climates the temperature remains unchanged at a depth of 3 ft. from the surface, from day to night. At 20 ft. the annual temperature varies but a degree or two. At 75 ft. below the surface the thermometer is perfectly stationary. In the vaults of Paris observatory, 80 ft. deep, the temperature is 53°. In tropical regions the point of unvarying temperature is reached at a depth of one foot.—JOHNSTON'S "*How Crops Feed.*"

> It is well known, that there is a limit of depth within which the variations in the temperature of the air make themselves felt. In temperate climates this is from 80 to 120 ft. Springs which rise at a lesser depth than 100 ft. have a temperature which varies with the seasons, whilst waters rising from a greater depth have a constant temperature, depending only on the heat existing at their source. Springs whose temperature is above the mean annual temperature of the locality, are called hot springs.—*From the German of* FRANZ SCHNACKHOFER, *Professor at Imperial and Royal School of Agriculture, Vienna, quoted in "Fuel and Water."*

> When the bed which forms the reservoir for springs is at such a distance from the surface as to be beyond the zone of season changes, and yet within that which is influenced by the climate, the water has a temperature equal to the mean annual temperature of the locality where it rises. In Britain this zone of constant heat is from 200 to 300 ft. deep. After this is passed, the temperature increases 1° for every 50 or 60 ft.—*Chamber's Encyclopædia.*

> If the thermometer be placed in a deep cavern, the variations disappear, and one uniform temperature is registered under all circumstances. What that temperature is, will depend principally on the climate of the locality, the constant temperature being nearly the mean annual temperature of the surface.—HUXLEY, *in "Physiography."*

It has been stated, that the temperature of the peculiar caves beneath the city of Paris, in one of which the great clock of the observatory is kept, some 80 or 90 ft. below the surface, is 50°. The mean annual temperature of the city is 57°. As we ascend mountains, the temperature decreases 1° for every 334 ft. The King's Chamber, in the Great Pyramid in Egypt, is about 300 ft. above the level of the adjacent plains, and is protected on all sides by 180 ft. of solid masonry. Its temperature is 68°. The mean annual temperature of Cairo is a little below 70°. Since the degree of heat in the stratum of "invariable temperature" so nearly agrees with the mean annual temperature of the locality, the following list may be interesting. The figures indicate the mean annual temperature in degrees Fahrenheit:

Toronto, Ont., Canada	44	Boston, Mass.	48
Quebec, Quebec	41	Cleveland, O.	49
Eastport, Me	41	Columbus, O.	53
Pembina, Dak.	35	Cincinnati, O.	56
Port Huron, Mich	45	Detroit, Mich.	48
Grand Haven, Mich	47	Erie, Pa.	50
Burlington, Vt.	46	Philadelphia, Pa.	53
Milwaukee, Wis	45	Chicago, Ill	49
Buffalo, N. Y.	47	Des Moines, Ia.	50
Portland, Me.	47	Leavenworth, Kan.	53
Newport, R. I.	50	Cairo, Ill.	58
Oswego, N. Y.	48	New Orleans, La.	69
Albany, "	48	St. Paul, Minn	44
Duluth, Minn.	40		

Of course, within a few feet of the surface the temperature will be higher than the above figures in summer, and lower in winter. On one occasion, when the outside temperature was 41° below zero, the air came in through my sub-earth pipe at 38° above; that is, in passing through 170 ft. of 9-inch sewer-pipe, laid about 5 ft. below the surface, the air acquired 79° of heat. I have observed that the air is not warmed quite so much toward the close of a cold winter, owing, I suppose, to the gradual cooling of the earth around the pipe.

There is an atmosphere circulating below the surface of the earth, as well as above it. This "ground air" extends down to the "ground water," the level of which is indicated by the level of the water in wells. The nature of "ground air" has been examined by Prof. Nicholls (see Sixth Report of Board of Health, for Massachusetts, for 1875) and others, and it is found to be so very rich in carbonic acid that, at a depth of 13 ft., it is sometimes irrespirable, and will extinguish a light. The amount of oxygen is found to be in a measure inversely as that of the carbonic acid. It is this soil air which sometimes proves fatal in deep wells, and not carbonic acid separated from the air above, and sinking into the well by its superior weight, as is often supposed. Intelligent bee-keepers will at once see that, in order to bring pure air into the cellars, it will not do to use drain-tile for sub-earth pipes. Cast-iron water-pipes, or sewer-pipes cemented at the joints, should be used. A nine-inch pipe of the latter, 170 feet long, cost me about $110 when finished.

Ernest's experiments are watched with interest; but if he will look up Joule's experiments in determining the mechanical equivalent of heat, he will see that the temperature of the water in the pail, after being pumped up, was not exactly the temperature at the bottom of the well, 97. ft deep.

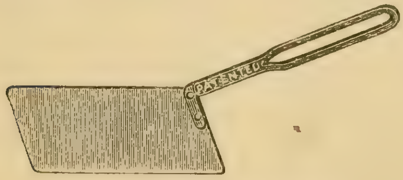
Lindsay, Ont,, Canada, Feb. 1, '86. S. CORNEIL.

I am sure, friend C., that we are very much obliged indeed for the very full and complete manner in which you have discussed this matter of the temperature of the earth. In regard to your caution, however, at the close of your article, it seems to me that carbonic acid is not common enough at a depth of from three to five feet to make it necessary for us to go to the very great expense of either iron pipes or burnt sewer-pipes with cement joints. I confess that I have never before understood how it was, that carbonic acid came to be present in wells and mines.—There is one point, and the one that concerns us most, in regard to this matter of the temperature of our earth, and I think it has hardly been touched upon. It is this; for protecting bees or other domestic animals, it is not necessary for us to go into the ground so far that we have an absolutely unvarying temperature. A very little banking of earth makes quite a difference, I have discovered, and all we need to do is to make our cellars or outdoor caves with their sub-earth ventilating-tubes deep enough to get pretty nearly the temperature we desire. If I understand you correctly, the temperature I gave of Mammoth Cave was not to be taken as a guide to the mean temperature of old Mother Earth in all localities, but simply the mean temperature of that part of Kentucky.

A HONEY-KNIFE FOR ONLY A DIME.

SOMETHING FOR BEE-KEEPERS WHO HAVEN'T MUCH MONEY.

HOW often do we find a tool, worth only a few cents, that will do the work of one that has cost a dollar or more! I have sometimes had such an experience, and felt out of patience with myself to think it never occurred to me that a cheaper form would answer every purpose. Below is a picture of a honey-knife that illustrates the point.



OUR TEN-CENT HONEY-KNIFE.

The blade is made of a thin slip of steel, in the form shown above, 2x4½ inches. The handle is made of malleable iron, securely riveted to the blade. The blade is so thin that but a very few strokes of a whetstone, oilstone, or even a scythestone, will give it a keen edge, for there is so little steel to grind away that the sharpening can never be a laborious process, and yet the quality of the steel is so perfect that it seems almost impossible to bend or injure it. You can sharpen it on one side or both sides, as you choose. You can use it for uncapping, or for cutting up combs in transferring; and for the latter it is, in my opinion, superior to any other knife made, at any price. For scraping off wax from honey-boards, tops of frames, shipping-crates, or even wide frames and sections, no other tool has been brought out any thing like it. The wide-pointed putty-knives we have sold so extensively for the purpose come pretty near it. But this answers every purpose of the putty-knife, besides being a honey-knife that may be equal to any. The sharp point will be found to be very convenient for a great variety of purposes; and after all, if you leave it out in the rain, or forget it, you are only ten cents out. A good many times I would give ten cents for a new one, rather than go after the old one, when it happens to be some little distance away. It seems to me it would pay almost every bee-keeper to have three or four of these handy little implements; that is, if he has a good many hives. We notice the cut is marked "patented." This was done by the inventor, who intended it for a knife to use in the kitchen. But if you pay the ten cents, you can use it in the kitchen, or out among the bee-hives, just as you choose. I shouldn't wonder if it would pay you to get one for your wife also. Price 10 cts.; 5 for 45 cts.; 10 for 80 cts.; or 100 for $7.50. If wanted by mail, add 5 cts. each extra for postage.

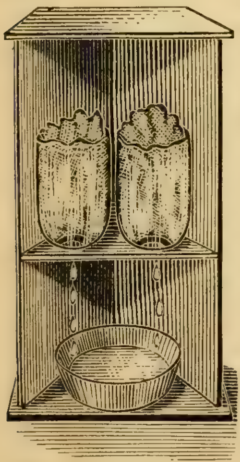
REVERSIBLE BEE-HIVES AND REVERSIBLE FRAMES.

SINCE the description of Heddon's hive and arrangement, so many letters have come in, describing hives and various arrangements for reversing hives as well as frames, it begins to be almost beyond my strength to go through the descriptions and give an opinion of them. The greater part of them are nothing particularly new. Years ago, Dr. Conklin, of Delaware, Ohio, sent me a hive to try, which had frames perfectly square, and set in the hive so one corner of the frame was down. These frames could be used with any one of the four corners down; but all the time I used it, it never occurred to me to take advantage of the ease with which these frames could be reversed. At the Ohio State Fair last fall, Mr. A. C. Benedict, of Bennington, O., had the hives on exhibition, with such frames. He has used these frames, I believe, for twenty or thirty years; and although they can be placed one side up just as well as another, he has never practiced reversing them. He says he does not want them reversed. Is it not a little singular, how progress and improvement and fashions revolve around, and once in about so long a time they come back to about the same old thing again? Even shallow sections, and hives used one above the other, have been in use for years, and have been repeatedly patented. Our old English works give pictures of them now; and before the advent of movable frames it was customary to have shallow hives with just the same depth of comb that Heddon uses, and these were worked two tiers, three tiers, and even four tiers high. Some of them used slats to induce the bees to build their combs regular, so that the owner might hold these shallow sections up to the light and look through them. A good many are working at a plan for movable frames that may be lifted out, no matter which side up the hive happens to be. I don't believe, friends, I would waste very much time or money on this matter just yet.

A NOVEL WAX-EXTRACTOR.

AN INVERTED FRUIT-JAR WITHOUT BOTTOM BEING USED FOR THE PURPOSE.

READING the article on p. 855, on the above subject, caused me to smile over an experience of several years ago. I wanted something to put bits of comb in, and scrapings, to save them (I was not home), so I asked for a pan, but soon found out "any thing was good enough;" and, chancing to see an old two-quart fruit-jar without bottom, and with the top on, I took that and set it bottom up. It being a warm sunshiny location, the more I put in the jar the more it settled, and soon began to melt; and in three or four hours there was perhaps a pint of as nice melted wax as ever ran out of comb. The jar-top being metal, a steel point soon made several holes in it. This I placed over a pan on a board with a hole in, and it soon gave a cake of wax. The fruit-jar extractor made quite a laugh on me, and stopped the women-folks from sputtering about the "nasty muss of wax-making." There have been more than 20 of those little wax-extractors made in the last seven or eight years. The first one gave birth to more improvements, so that now some are being used thus: Take a piece of coarse wire cloth, crowd it down the can; on top of that some fine wire cloth like queen-cage cloth, then another piece cut a little large and put in so as to bulge upward, and your jar is ready. For the stand, cut two boards 14 in. wide and 24 inches long; two boards, 14 in. square, and a triangular piece 12 in. on two sides. These sides meet and form a right angle. Bore a hole in the center of the triangular piece, large enough to let the top of your fruit-jar in, or two holes for two jars. Nail the two long pieces together, and to the ends nail the two pieces 14 in. square, as shown in the cut. Now, 10 in. from the bottom, nail the triangular piece. The adjoining cut will make the matter all plain. Into these jars I have put bits of comb honey, and even old brood comb will clean up in tiptop shape. As old bottomless fruit-jars are generally handy, or even large glass bottles or demijohns, the time, making, and expense of the woodwork is small. As a preventive of worms infesting the wax, it is a saving over keeping the bits till enough to pay for melting, and I think more wax is actually obtained. The amount of honey run through is not going to make robbing, because it is always in that place, and the bees will look for some every time work is being done. The bees are always peaceable about it.



THE FRUIT-CAN WAX-EXTRACTOR.

The extracting is not all it is good for. A few bits of smoker wood can be kept dry in the back corner under the three-cornered piece. It is a stand upon which to put queen-cages, a smoker, or dozens of other things. Two fruit-jars, mounted as I have described, will keep every thing in the shape of comb and broken honey all melted up, from an apiary of 20 to 50 colonies. One of the extractors will run off from 5 lbs. to 25 lbs. per day. I have seen 4 lbs. run through two of the 2-qt. cans in one hour, all from the bits of new comb, drone brood, scrapings of boxes, etc. So you see they are not so slow after all.

DISTURBING BEES IN WINTER, NOT ADVISABLE FOR THE NOVICE.

In your foot-note to G. M. Doolittle's article, p. 856, you say, "Bees can, perhaps, be handled successfully;" in other words, examinations can be made during winter upon the bees for scientific purposes. Well, I can tell you, beyond doubt, that it has been done without any apparent harm, and, like Mr. D.'s case, seemed beneficial in result. In the winter of 1883 one hive was examined almost daily, regardless of the weather; and from 1874 to 1880 there were perhaps a dozen hives experimented with without loss, to ascertain the heat of the bees during various changes, and how far the hoar frost would reach between the ends of the combs; the comparison of differently constructed hives, thick and thin lumber, and in various exposures, and how much more honey a swarm being often disturbed would consume than one let entirely and severely alone. Successfully examining hives for various purposes, forces myself and others to say to all but the expert, "Let them alone from the time of packing till the cleaning-out in the spring, during good flying weather, because, so far as I can learn, there are more queens spoiled, and more stocks made queenless, by the improper handling of the bees in the spring, than from any other cause, and yet every man knows what he is doing, in his own mind (I find many such among novices), because Yankee ingenuity is, in very many cases, conceit."

ABSORBENTS IN WINTER.

Mr. Heddon, on page 854, referring to moisture, reminds me of experiments relative to the use of wet cloths, and that the amount of seemingly air-tight sealing can be successful, and under what conditions. In 1878 I repeatedly took out and exchanged many of my top cushions, to dry them, and I always found them wet on the upper side. This induced the experiment of melting sugar into a solid block, made by pouring the liquid into a frame, and placing over the cluster; give no other food, and contract the space of the bees to the lowest point. Then envelope the whole in a non-porous material, to prevent the escape of any moisture. The hive is in this manner thoroughly packed and protected every way, and gives only a small entrance, thus causing a condensing of moisture on the slab of sugar. This furnished abundant liquidation for the winter supply, without an apparent cause of the bees going for water; but for this purpose, hermetical sealing of the division-board spaces is necessary as all others, or the side packing will take up what would pass out at the crack at the ends of them. This proves that, without close attention to minute details, success turns into failure.

H. L. JEFFREY.

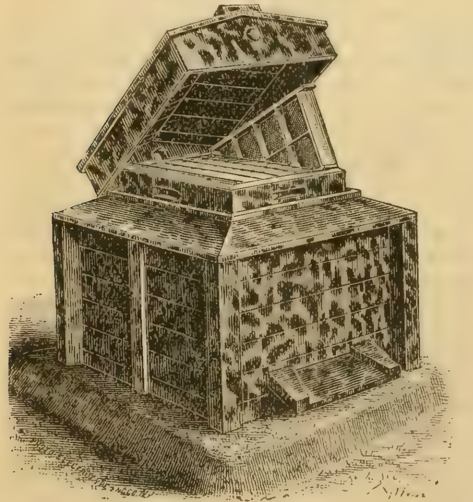
New Milford, Conn., Dec. 23, 1885.

I would suggest, as an improvement to your trough, that the inside be lined with tin. This doubtless would add very materially to its working power. It is not all of us who have jars lying around and broken off just at the right place for the above purpose. Having had some experience in working glass for chemical purposes, I will explain, for the benefit of those who may not know, how the bottom of jars can be removed. Around the jar where you wish to sever the bottom, draw the point of a red-hot poker. As the latter passes around, the glass will crack. In place of the 2-qt. jars mentioned above, you can purchase very cheaply at the drug-stores a gallon bottle. While this would add but little to the expense it would be much more convenient for taking large pieces of old comb. ERNEST.

A MOVABLE BOX IN UPPER STORY OF CHAFF HIVE.

FRIEND BISH GIVES US HIS EXPERIENCE IN THE MATTER.—SEE GLEANINGS, P. 12, 1886.

MY experience of three years with movable upper stories tells me that a box can not be tolerated. First, its thick lower edge kills too many bees in putting on. It is a box you can not use for any other purpose. But the Simplicity body does away with both objections. Friend Cross, on page 12, 1886, proposes to make a chaff hive longer, and to utilize vacant space at sides, with brood-frames. I find an objection there. It leaves a loafing-space for the bees between the wall and box, and they are sure to get in the way every time the cover is removed, taking time to replace it. I find the best remedy is (where new hives are being made) to change the dimensions of the chaff hive so a Simplicity body just goes inside of upper story, leaving ¼ or ⅜ inch space all round, and the lower story of proper breadth to hinder the bees getting up. Below is a cut of a hive I am making, especially arranged to take a Simplicity hive in the upper story.



THE C. P. BISH CHAFF HIVE, SHOWING THE SIMPLICITY BODY, FILLED WITH SECTIONS.

The hive as now made is 3 inches narrower than the one the above cut was taken from.

The outside of Simplicity body, 15⅝ inches, is just right for lower story; the double wall of upper story of chaff hive is only six inches high, instead of ten. Six inches is sufficient room for a cushion in winter, and makes it handy to catch the hand-holes of Simplicity body, and not so high to work over. The cover will have to be deeper, to make the difference. I find some colonies of bees build some comb between top-bars and bottom-bars of frames, and some do not. The space is Simplicity space, of course. C. P. BISH.

Petrolia, Pa.

Friend Bish, your idea of making the chaff hive lower, and making the cover a little higher, so it is, in fact, virtually the same thing as a cover for a 1½-story hive, is quite an idea, and no doubt it will answer just about as well for wintering as the full depth of the hive. The only objection that I know of is, that you do not get as many sections as where the wide frames are hung directly in the upper story, as we have them; and for extracting you would not get as many combs in the upper story for surplus. As it makes a little more machinery, I think I should prefer our style. Your mottled hive looks very pretty, and that a good substantial alighting-board is also a nice thing to have, as we know by experience.

MOVING BEES IN COLD WEATHER.

HOW TO CORRECT FALSE STATEMENTS.

I MOVED seven colonies of bees twelve miles on the 13th of Jan., when the temperature was 10° above zero. This was a day or two after the noted four days' blizzard. I used a sled, as the sleighing was excellent; no mishap of any kind, and the bees are to-day in the very best of condition (in cellar). I shall now have an opportunity of testing the amount of injury, if any, in moving bees in mid-winter. Of the 61 colonies I have in cellar there has as yet been no water dripping from the entrances, as is sometimes the case. I attribute this to the fact of maintaining a higher temperature in the cellar. With the exception of a few days, I have kept the temperature at 46 to 50°.

The false and sensational statements going the rounds of the papers, regarding comb honey being manufactured, and put on to the market, are having their effect, and no mistake. I was somewhat annoyed, some time ago, by hearing a very prominent merchant explaining to some very interested listeners, how, that "nowadays they manufacture the very nicest kind of comb honey without the aid of bees, etc." Of course, I "took the floor" when he got through, and in less time than I can write it I corrected him, and he confessed that he did not *know* that it was so, but that he had read statements to that effect in the papers. I took the opportunity to explain that the manufacture, by artificial means, of comb honey, was entirely beyond the possibility of the most advanced art; and I also referred him to your $1000 challenge for positive evidence of such manufacture. Now, when we come to reflect a moment over the wonderful achievements in the arts and sciences of this progressive age, we need not be at all surprised that the reading public, who have no practical knowledge of apiculture, will readily believe that the successful imitation of the nicest comb honey is entirely within the possibilities of modern science. One of the successful ways to correct this damaging misapprehention is for bee-men everywhere (who can rightly handle the subject) to furnish articles to their county and local papers, which will readily be admitted, and in strong, clear terms, meet this popular error. There is no use to meet it in an abusive manner, but, rather, in that kind and candid manner that invariably carries conviction.

Another way to meet the matter is for honey-producers to guarantee every pound they sell to be absolutely pure. I have no fears as far as one's local custom is concerned; but when one has "a bit" more than he can dispose of at home, is where trouble seems to be ahead.

8—D. E. BRUBAKER, 31—61.

Maxwell, Iowa, Jan. 28, 1886.

Friend B., your suggestion is wise and sound. The celebrated Mr. Edward Murphy is now holding a series of meetings in Medina; and his great stronghold—in fact, the one great thing that gives him such wonderful power in banishing intemperance from our land is, that he deals directly with the *people* instead of laws and legislation. If he can get every man, woman, and child, in a town to wearing the blue ribbon, indicating they have signed the pledge, saloon-keepers would have so little custom that they would pull up stakes and move, or quit the business. The number who would violate a pledge, with their own signature at the bottom of it, would be too small in almost any community to support saloons. Well, now, if we can get the truth of this matter before the people, in regard to artificial comb honey, by inducing local papers to correct the statements, the whole thing will die a natural death, and it seems to me this is the way to do in dealing with any kind of sin—strike it where it starts, right in our homes, and in our family papers.

DO IMPORTED QUEENS PAY?

FRIEND DOOLITTLE'S EXPERIENCE IN THE MATTER.

TO the question in editorial (page 75, GLEANINGS for Jan. 15), "Do you get more honey from Italian bees, say one or two generations from Italy, than from stock bred four or five years in our own country?" I answer, no; and, as a rule, not as much. From the experience I have had with the imported stock as above (having had only one imported queen, but many from different breeders that were reared from an imported mother, besides those reared from the one I had) I much prefer queens reared from their best strains of home-bred stock by N. N. Betsinger, Dr. G. L. Tinker, Aaron Benedict, Dr. J. P. Wilson, J. M. Brooks, and others, to any of the imported stock I ever saw. The men named above are breeding bees for quality, and the bees show it by the large yields of honey they bring in, while the imported stock show that no care is taken in breeding them.

For the last twelve years I have been breeding for the sole quality of honey-gathering, and to-day I would not trade one of my best queens for any dozen of the best queens from imported stock I ever saw. What gives vitality to our stock is a direct cross rather than in-and-in breeding, and this is what gave the imported stock so much favor a few years ago. Prior to this time, parties in the U. S. had bred in and in for color, until a feeble race was the result; and, fearing that the Italians were to run out, some of them went to importing again. What was the result? The young queens from the imported queen mated with the drones from the home-bred stock, which gave a direct cross, thereby giving great vitality to the bees, and the cry was raised that queens from an imported mother were superior to those bred in our own country, causing it to come to pass that a breeder must advertise with a * in front of his name, if he would secure any patronage.

The claim, that hybrids were superior to Italians, came about in this same way, as here was a direct cross again. Fully realizing that this was wherein the matter of vigorous bees rested, I began, ten years ago, to purchase one or two queens each year of different breeders whom I believed had a good strain of bees for honey-gathering, this belief being founded on a good average report from their apiaries year after year. After purchasing, these queens were tested one year, together with two or three of their daughters, and, if found of value, some of such were used to partially stock the apiary with drones; and if any were superior, queens were reared from them to a limited number, never letting go of the advance I had made with my original strain, but, rather, keeping this ahead all the while by adding what of value I found in those I purchased. In these tests it more often happened than otherwise, that the queen I purchased proved so much inferior to my own that I was obliged to kill them, much as I disliked to do so. One case in particular which I recollect was where I purchased, at a very high figure, an extra selected tested queen which was so inferior as a layer that I did not use her at all. I kept this queen three years, and in none of these years could I coax her to lay in more than three Gallup frames, and the two or three queens I reared from her were little if any better, so I killed all of them. My original strain came from A. I. Root, about twelve years ago, together with a queen purchased in 1871 of Rev. H. A. King, then of Nevada, Ohio. Both of these queens lived to be over five years old, and showed such superiority that I have tried to perpetuate and improve upon it ever since. Then I added largely to the value of this strain by the queen of the "red clover" stock sent out by A. I. Root later on, which stock was of great value to cross with, although at the present time red clover does not blossom at all with us, owing to a midge in the head.

In the above I give the reader a little insight into the plan I have been working on, and I believe it to be the plan worked upon by many of those who are breeding bees for honey; at least, the bees produced by queens purchased from those mentioned above show that they are working on this or some other good plan. That the bees from imported stock are so variable, and show that no pains has been taken in breeding them, together with their lack in giving me as good yields of honey as do other queens, and those of my own, is the reason I have said, for several years back, that it does not pay us to import queens. G. M. DOOLITTLE.

Borodino, N. Y.

No doubt you are right in the matter, friend D.; but I am sorry you have not tested in your own apiary a larger number of queens received direct from Italy. The supposition has been, that nature has selected the fittest, on account of the comparatively barren climate of Italy compared with our own, and we wish to know whether this accords with the general experience of those who purchase queens to stock their apiaries. To get at all the influence of a cross of the blood, we want, also, to watch the progeny of the queen herself, and see if that progeny has as much vim for honey-gathering as succeeding generations.

A REPORT ON WINTERING, FROM MRS. AXTELL.

Something in Regard to the Best Temperature for Successful Wintering.

A BEAUTIFUL SIGHT.

IN our bee-cellar is a sight I feel tempted to look at more than a second thought would tell me was best—that is, best for the bees. It is the nice large cluster of golden beauties, clustered nearly down to the bottom-board of the hives. Some are on the bottom-board, while others have, as winter progresses, gone up higher. One feels tempted, almost, to thrust in his hand and pat the little fellows. The small colonies seem to go up higher among the combs, and more dead bees are on the bottom. The large colonies that go nearly or quite to the bottom have no dead bees, but there is half a teaspoonful or more of very fine pellets scattered very evenly over the bottom-board.

The front boards of the hives in the cellar were raised from one to two inches to give larger entrances, so the bees could better throw out their dead bees; the brood-combs are also raised about one inch higher from the bottom-board of both the colonies in cellar, 74, and those outdoors, 61, as we had so many colonies last winter when taken from the cellar that the whole bottom was filled with dead bees, and sometimes up between the combs. Our hives, you know, are clamped at the corners, not nailed.

It is a real satisfaction to thus look right into the hives and see them look clean and well; for one can tell almost as easily whether a bee is sick or well as he can tell whether a person is well or not. I have an idea, that when a bee gets sick he crawls out of the hive to die, generally, as in the summer time, does it not? If the most of the bees that are dead upon the floor were healthy bees, then it seems to me it would be well to devise some plan to prevent their getting out upon the floor. Broad alighting-boards, with strips of tin around the outer edges, might do; or perhaps a better way would be as mentioned in Mr. Barber's plan—pile the hives up in one solid body; but, what would they do with the dead bees? It seems to me it must be very annoying and unhealthy for the bees to have a lot of dead ones in their hives.

We have kept the temperature in our cellar higher than ever before—from 40 to 45, and the bees crowded down to three and four combs, and on the sides of the combs, and on top, closely covered with oat or buckwheat chaff. We are surprised at the bees being so quiet at that temperature. I am satisfied we have kept them too cool before—about 36.

Since the last cold weather, we have had a fire in one end of the cellar, with quilts hung up against the ends of the hives, to keep the light from striking them, and to throw the heat over the top, so the nearest hives may not feel much the warmest. The weakest hives were packed nearest to where the stove is. The thermometer was sometimes in the center, and sometimes in the further end of the cellar. To-day it rose to 48, and yet the bees are quiet, occasionally a bee flitting out; but we have kept the sub-earth ventilator closed, and all other ventilation cut off. The heat from the stove makes the cellar feel comfortable, and the sides of the wall are not covered with frost, but are dry, which would not be the case with no fire.

My husband will report when he has made a more thorough test of temperature in the cellar and sub-earth ventilation. MRS. L. C. AXTELL.

Roseville, Ill.

I feel sure, my good friend Mrs. A., that a temperature above 40 will be better if you can keep the bees quiet; and I am quite sure I prefer 48, if not higher, unless a lower temperature seemed to keep the bees more quiet. When we wintered in the cellar, I thought more bees got out upon the floor when the temperature got up to 50 or 55, than when it was a little above 40. Your plan of giving abundant ventilation below, is something in the line of friend Green's article, if you will remember. We shall be very glad indeed to have further reports.

FEW OR MANY COLONIES: WHICH?

RED-CLOVER QUEENS, ETC.

I WAS much interested in Mr. Doolittle's article with the above heading on page 13 of GLEANINGS; but there are some points in his reasoning with which I can not agree. If he really advocates that the apiarist shall keep but 50 colonies in one apiary, and devote his entire time to the effort to produce large yields of honey, I would *not* agree with him; but if he means that the apiarist shall have several apiaries of 50 colonies each, I would agree with him.

Taking the first view of his argument, it has a tendency to make us believe that one swarm of bees, *if only large* enough, and expertly managed, would produce all of the honey the apiarist could dispose of! But, let us take 50 swarms, his lowest number, and see if the man who makes the raising of honey his only source of income, can make a satisfactory financial success of it.

We will take it for granted, that the person understands the secret of having his bees all in the best possible shape to secure the honey when it is secreted in the flowers. As I run my bees for extracted honey, and as my locality is perhaps not so good as Mr. D.'s, I will put my average yield, year in and year out, at 200 lbs. This would give me a yearly yield of 10,000 lbs. This amount, at the rate extracted honey is now selling at wholesale, would net me $500 per year. Now, an economical family could probably live upon this amount; but it has been said, that a person capable of successfully caring for 100 swarms of bees, or, if you please, 50 swarms, is capable of earning $1000 in some other pursuit; and I think every bee-keeper making it a specialty would not be satisfied with a smaller income.

Now, Bro. D. may clear much more than that amount rom his small apiary of 50 or 60 swarms, because he has a large queen-traffic, and there is no need of his establishing another apiary; but if he depended entirely upon his *honey* for an income, the attention he gives to queen-rearing would be well employed upon another apiary, if he had four apiaries with 50 colonies each, and obtained only 100 lbs. per colony; 20,000 lbs., at 5 cts., equals $1000. He would be better off financially than if he stuck to his 50; but if he can make his apiaries yield 200 or 400 lbs. per colony, he is so much better off. Again, 200 or more colonies would require but a slight increase of honey per colony to add many dollars to his pocket.

Every bee-keeper who has bees in different apiaries knows that a locality six miles away will yield, sometimes, much more than the home yard. To take advantage of these extra yields, the apiarist *must have* more than one apiary. Another reason why the apiarist must raise larger yields than 50 swarms can produce, is the cheapness of the product. It is now at a price where it seems it will not pay to adulterate it, and the outlook for the future gives us no hopes for higher prices.

A few years ago, and at present, there has been and is a cry against the small honey-producer. He has five or ten colonies of bees; and just as soon as he gets a box of honey he trots off to some grocery and trades it off for tea or sugar, at the grocer's own price, which is usually very low, thus setting the price for the specialist, who wishes to sell in the same town. But, let us look upon the other side, and see what the large producers are doing. Here is a man who has 800 swarms of bees in several apiaries. Perhaps it costs him $1000 to run those different apiaries; but his yield is 20 tons of comb honey. He can not afford to peddle it around to Tom, Dick, and Harry, but sells his entire crop for, say, 10 cts. per lb., thus getting a profit of $3000. Now "*I rise to inquire*," Where is your man with 50 colonies, trying to make a living out of them? Between the large producer and the small one he is ground to powder. The price for his honey is set by the former in the cities; by the latter, in his own town. He has got to continue his business with something else, or go into it deeper or step down and out. Every person who is making money in the bee-business at the present time is a large producer, or else is a large queen-breeder, or a large manufacturer of supplies. I speak for the present. Bro. D. speaks in a certain sense for the future. I hope the time will come when one swarm, if large enough, will produce tons of honey; but suppose we have an extra severe winter, or some other unexpected severity, our one swarm, or, if you please, our 50, will die—we are out of the business suddenly; but if we have 400 or 800, the chances are that we shall have 100 or more left with which to commence the season. We also find that those large yields of honey of from 500 to 1000 lbs. from single colonies are events of a lifetime. A few years ago B. F. Carroll, of Texas, reported nearly 1000 lbs. from one colony; but we may scan the pages of the journals as close as we please, and we don't hear of its repetition. It is just the same with nearly all of these immense yields. Our kind friend, the editor of GLEANINGS, obtained an immense yield from his entire apiary, and astonished everybody, long before GLEANINGS was born, and he even now occasionally refers to it; but we don't hear of his repeating it. Perhaps it is because from 300 to 500 colonies are kept in one apiary, and for this cause our friend has to buy California honey by the carload. But, Bro. Root, if it is such a fine thing, please reduce your apiary to fifty colonies, and give us another rousing report.

In the foregoing I have not entered into detail in relation to the cost of running an apiary for extracted or comb honey. My experience teaches me that it costs less in help, costs less in packages, less in shipping to market; the swarming fever is largely controlled, and I can sell honey in ton lots for 5 cts., if our comb-honey producers can for 10 cts., therefore if an apiary is run either way, the profits will be about the same; and with present methods and appliances, I think the large number of colonies, although they may consume 60 lbs. of honey per year, the little laborers are worthy of their hire, and are giving, in many apiaries, better results financially than the few.

As previously stated, Bro. D. speaks of the future, when the coming time and the coming bee will have arrived to stay. Even then, when that time comes, in whatever shape, round, rectangular, triangular, or reversible, or when the bee comes that will work upon red clover, and each one of our 50 colonies produces 1000 lbs., hundreds of bee-keepers will look over into the unoccupied field in an adjoining town, and, with characteristic enterprise, plant a successful apiary there; but the glorious day has not dawned, even though some claim to rear red-clover queens.

RED-CLOVER QUEENS.

I do not wish to impute actual dishonesty to the breeders. There may be a plausible excuse for them to so name their queens; neither do I deny that they have a valuable strain of bees. You will notice a remarkable coincidence. These queen-breeders all live in localities where red clover is raised for seed. The seed is secured from the second crop: this crop might be termed out of season, and, owing to the strength of the flower going to the production of seed, the flower is much smaller, and the secretion of honey much less, and the bees work upon it to a certain extent, but, we claim, not more than any other good strains of bees. I have even seen black bees working freely upon red clover.

It is, futhermore, a remarkable fact that the yields of honey in the immediate vicinity of these *remarkable* queens is not larger than in other localities. It would be a fact beyond controversy, and convincing, if the bees could obtain honey from the first crop of red clover, for each swarm would make such astonishing yields that every bee-journal would shout over it. The papers would hatch up a story about the bee-keepers making artificial red clover, and setting the roots in sweetened water. Bro. Doolittle could sit down under his own vine and fig-tree by the side of that 50 swarms, and sing pæans over his thousands upon thousands of pounds of honey. The reader will now bear in mind that this is a remarkable age. Every new thing should be investigated; and when you spend your hard-earned dollars for an article of which you have something as good, if not better, in your own apiary, you feel like saying right out loud, "Humbugged again."

J. H. MARTIN.

Hartford, N. Y., Jan. 29, 1886.

Friend M., in your estimate of the honey received from 50 colonies, you say nothing about increase of stock, and I believe it is generally conceded that as much honey can be secured with a moderate increase of stock as by holding the original fifty down to absolutely no increase.—I think you are a little severe on red-clover queens, although I agree with you that, when the seasons are favorable, all kinds of bees, almost, work on red clover. In our locality, Italians, and oftentimes blacks also, are to be found on the red clover in June, almost as much as on white clover—sometimes more, although there are seasons when the bees work strongly on the white clover, and almost not at all on the red clover. I think I have often stated, that, in my opinion at least, most of our clover honey in Medina Co. comes from red clover. It is true, however, that when the white clover ceases to yield honey, the red clover ceases also, and occasionally we have a season when bees get honey enough in September from the seed crop of red clover to fill section boxes, although this latter does not happen, perhaps, oftener than once in five years, on an average. There are strains of Italians that seem to gather more honey in September than other strains, and we suppose, from the color and taste, that it comes from the seed crop of the red clover. The effort, however, to perpetuate a strain of bees that will gather honey from red clover at times when other strains do not, has never been very fully realized, so far as I can learn. Most of the bees from an imported queen, direct from Italy, usually gather more or less stores while the seed crop of red clover is in bloom.

I did not know that good honey was ever sold as low as 5 cts. for extracted and 10 cts. for comb. If any one has any good honey to be sold at those figures, I should be glad to take it off his hands, no matter how much there is of it; and if it is not too remote, I will pay freight besides. A pretty large crop of honey can be sold at retail so as to get 10 cts. for extracted and 15 cts. for comb honey in almost any locality, by taking a little pains; and I think it will pay almost any bee-keeper to develop his home market, *any* way.

CELLAR WINTERING.

UPWARD VENTILATION, LOWER VENTILATION, SUB-EARTH VENTILATION, ETC.

BRO. ROOT:—I'd give seventeen cents if you wintered your bees in the cellar. It may be best for you to winter on summer stands; but for many of us it seems best to winter in cellars; and if you did so, I am confident you would help settle a good many questions that would tend to make cellaring less uncertain. I should very much like to have your help on the ventilation question. Opinions conflict as to the necessity for any kind of ventilation, some seeming to consider it as *the* important factor, others thinking no ventilation whatever necessary. When we consider in what almost absolute inactivity bees may be kept, it would hardly seem necessary for them to use much air; and instances are on record, if I mistake not, where bees hermetically sealed, or apparently so, have remained in good health. Conditions vary so much that I am far from laying down as a fixed rule for others what may seem best for myself; but so far as my own bees and cellars are concerned, in spite of my theory as to their needing little or no air, observation leads strongly in the direction of their needing a change, and a pretty rapid change, of air.

UPWARD VENTILATION.

Formerly the absolute necessity of upward ventilation was strongly urged by many, and I think a great majority believed in it, although a few combated it. Of late, very little has been said about it. Three or four years ago I tried some hives without upward ventilation, and could not see that it made any difference; and for the past two years I have given no upward ventilation, mainly because it was more convenient to leave the hives covered up tight. I supposed I was somewhat heretical in my views, until surprised to find in the *Canadian Bee Journal* of Jan. 20, 1886, that a radical change of sentiment had been quietly going on in bee-keepers' minds; for in reply to a question on the subject, not one of the fifteen who replied considered upward ventilation essential. The impression prevailed, that it made little difference where the air entered the hive, just so the bees could have it. My own hives are taken into the cellar with the cloths glued on tight, just as they were on the summer stands; but I have enlarged the entrances, so that, instead of ⅜, they are ½ inch in height, and the whole width of the hive. But if there is no good air in the cellar it is impossible to have it in the hive, so that hive ventilation is not so important to consider as

CELLAR VENTILATION,

About which comparatively little has been said. I may here mention some of the things that lead me to think cellar ventilation important. Please remember that I have now in mind cellars well filled with hives, piled five high. (When I had only eight or ten hives in the cellar there was no trouble about ventilation.) When I found the bees quite uneasy in former winters, I thought it was because they were too cold, and I was in the habit of building a fire in the evening. In the morning I found the bees nice and quiet, but was puzzled to find the thermometer no higher than it had been before I made the fire, which, being a wood fire, had died out in the night. If cold had made them uneasy in the first place, why were they not now uneasy with the same degree of cold? I came to the conclusion that the fire had hastened the ventilation of the cellar, and thus quieted the bees. Still, there may have some changes taken place, such as getting at their stores while the cellar was heated, leaving them quiet afterward, without any reference to the ventilation.

Toward spring, when the weather became warm and the bees uneasy, I opened the cellar doors and windows at night, causing great uproar among the bees when first opened; but by morning all were quiet, no change having taken place in the temperature. What, besides the change of air, quieted them in this case? Again, I noticed the bees were invariably quiet after a windy time, whether cold or warm; and a still, damp time was just as sure to make them uneasy. The shop cellar is without sub-ventilation; and when the weather moderates, it is necessary to open the trap-door or window; but in zero weather no such necessity exists, although the thermometer in the cellar may stand just as high as in the warmer weather. The reason is, that, in the zero weather, the temperature is so much higher inside that the heavy, cold air outside forced its way through every crack and crevice, thus ventilating the cellar without any large opening. Now, don't understand me to say that the whole secret of wintering lies in ventilation; I don't claim to know much about wintering, any way, and am far from thinking that perfect ventilation will secure perfect wintering. I merely think ventilation important, practical observation showing it more important than theory would lead us to believe. Nor is this disproved by citing occasional instances of successful wintering with no apparent ventilation, any more than occasional instances of wintering on five pounds of stores would prove the general practice of allowing only five pounds per colony any other than hazardous. Certainly no *harm* can come from having an abundance of good pure air in the cellar at all times.

Another consideration urging in the same direction is, that most bee-cellars are under dwelling-houses, and medical authorities inform us that grave consequences occur from impure air in cellars. If only a few bees are kept in a cellar it may not be necessary to make any special provision for changing the air, as enough cracks usually exist to allow a sufficiently rapid renewal. In this case, however, especial pains should be taken, both for the health of the family and of the bees, to see that no decaying vegetables or other matter should be left in the cellar, from which poisonous emanations may be constantly taking place. It is frightful to contemplate the amount of foul and decaying matter that is cleaned out of cellars every spring, if, indeed, it is cleaned out at all. Many never think of disturbing, until spring, the decaying mass, no matter how much noxious vapor is constantly steaming forth. The cellar should be thoroughly cleaned of every thing of the sort, and *kept* clean—fruit and vegetables of all sorts frequently picked over, and all decaying specimens removed. The cellar should at all times smell sweet and clean, and a good coating of lime or whitewash once or twice a year will help. If twenty or more colonies are kept in a cellar, special provision may be needed for renewal of the air, and of this I may have a word to say in a future number.

Since writing the above, GLEANINGS for Feb. 1 has come to hand, and your remarks about using sub-ventilation for greenhouses dashes my hopes in that direction, for I intended to make a great spread in talking about using it for greenhouses, hen-houses, and perhaps even for dwellings; for if we need to heat the air for *any* purpose, it will certainly cost less to heat it from 35 or 45° than to take it lower.

I heartily congratulate Ernest's wife on getting a good husband. I don't know enough about her to congratulate him, but I suspect it is all right.

C. C. MILLER, 179—340.

Marengo, Ill., Feb. 3, 1886.

Friend Miller, with the variable winters we have here in Ohio, I can not feel that cellar wintering would be profitable to us, although I may be mistaken. I have thought several times I would winter part of them indoors and test the matter carefully; but I do so dread lugging hives out and in, and having things torn up generally, as we usually have where we carry them into cellars, that, to confess the truth, I am very reluctant to undertake it, especially while we have such excellent success wintering on summer stands, and coming out with such strong healthy colonies.—If we use no upper ventilation, it seems to me we must have some sort of protection to keep the frost from striking the substance that envelopes the brood-chamber. In old-fashioned box hives, where no upward ventilation is given, icicles sometimes form on the sides and top of the hives, as large as your arm. Now, an outer covering would entirely prevent this condensation of moisture, and freezing into icicles. In regard to bees wintering in hives hermetically sealed up, Prof. Cook did make some such experiments, but I feel quite sure there were some cracks and interstices in the hives, either through the top, sides, or bottom, that gave them plenty of air. It is with hives as you aptly mention with cellars. When we have weather below zero, the air pours with great force through cracks and crevices that at ordinary temperatures would be called air-tight. I would have the cellars ventilated, anyway, whether the bees wintered well without ventilation or not. It may be that some cellars, on account of natural circumstances, are already sufficiently ventilated, without ventilators or sub-earth pipes. This might be the case in sandy soils; but in our water-soaked clay soils, in the winter time, it seems to me ample arrangements should always be made for ventilation. The point you make in regard to saving fuel and saving food by bringing fresh air into our cellars, greenhouses, and dwellings, after it has been warmed many degrees by the earth, is certainly a very important item—yes, for the hen-houses, horse and cattle stables, and everywhere where we keep domestic animals. Zero air and ice-cold water is a great waste of animal heat, and, as a necessary sequence, a waste of grain and other food products. Friend Terry, in his forthcoming book in regard to the care of domestic animals, will give us some grand new thoughts on this subject.—Our discussions in reference to the temperature of Mother Earth, sub-earth ventilators, etc., have a value that is going far beyond the wintering of bees, alone.

THE YAZOO VALLEY, OR DELTA.

ITS HONEY RESOURCES.

ONE of the most interesting sections of Mississippi is the Yazoo Delta, not only in respect to its general agricultural capacity, but also to the bee-keeper for its honey resources. I have been acquainted with this part of the State from my youth up, my father having moved, when I was a small boy, from East Mississippi, with his slaves, and opened a plantation on the Tallahatchie River, which plantation I still own, and rent in part to the slaves, now freemen, who formerly cultivated it. I, of course, never made observation in the country with reference to its honey capacity until I became acquainted with bee culture. Until 1876 I knew nothing of bees, only as insects placed at a remote corner of the yard or garden, and to be severely let alone except occasionally, when robbed to obtain a dish of honey for the table. In that year I casually obtained a volume of "Langstroth on the Honey-Bee," and since have, when on my plantation, been carefully noting the honey resources of the "Swamp," as we commonly call it. I have known of large apiaries of black bees down there in common box hives, and have seen some beautiful white honey; but nothing is known, as a rule, of modern bee culture, the Italian bee, extractor, movable-frame hive, etc. Dr. Blanton and a few others keep bees scientifically, in this valley. My conclusion from my observations is, that its honey resources are immense; and my aim is to establish an apiary there as soon as practicable. As honey is a very general product of nature, it might be expected that a country with such exuberant forest growth, and inexhaustible and unsurpassed fertility, should yield largely the vegetable nectar which the bees refine and evaporate into honey. The climate, too, is highly favorable to large secretion of honey each year, without fail. The Swamp is pre-eminently the cotton section of Mississippi, but I have never known bees to gather honey from cotton to any extent. The cypress and willow and honey-locust and black gum are very abundant, and yield much honey. The rattan is everywhere, and is alive with bees in early spring. Attracted by the hum, I have at times stopped, spellbound, for a long while to watch the bees gather honey from this plant. The cross-vine, or swamp woodbine, is very luxuriant, and its rich festoons of white flowers hanging from tall trees furnish much forage to the bees in midsummer. But my attention has been most attracted by the tupelo gum. This is a tree with large base, but with small, tall, and tapering body above, that grows only in very rich sloughs, where the roots are under water. The flowers are white, and grow in large festoons. They send out a delicious fragrance to a long distance upon the air, and yield much beautiful white honey. I might also mention the persimmon, hackberry, and other trees and plants; but the above enumeration will give a general though very imperfect view, for doubtless there is a vast number of plants that yield honey that are not yet compassed by my knowledge.

I may add in conclusion, that there are very bright prospects in every way before this valley. The levees are in good repair, a fine railroad runs through it on the west from Memphis to Vicksburg; the Illinois Central R. R. is building a branch from Yazoo City up the Yazoo and Tallahatchie Rivers to Memphis, and another road will connect these two. Thus the whole valley will be intersected by railroads; the Father of Waters will be kept within bounds, and we who are interested say the valley will become very thickly inhabited, and will be made the garden spot of Mississippi.

Grenada, Miss. OSCAR BLEDSOE.

FLORIDA, AGAIN.

THE PROSPECTS AFTER THE LATE FREEZE.

I HAVE often used the columns of GLEANINGS as a medium through which to encourage good men to come to this State to look up the bee-keeping interest here, and, in consequence, many have come and made happy homes; others, coming with great expectations and little "sticktoativeness," have been disappointed at first glimpse, and returned north, to regret their hasty decision. Still others, after coming here and taking a fair look at the State, have decided that, all things considered, they had best remain where they are, rather than make pioneers of themselves and have to put up with all the inconveniences to be met with and endured in "growing up with a new country." I have always endeavored to convey as correct ideas of this country as possible in all my writings; and for fear that many might, through the writings and advertisements of unscrupulous land agents and speculators, have formed ideas respecting the State that would cause them to see more encouragement in my letters than I intended to convey, I have always advised a visit of inspection before disposing of valuable property elsewhere. Notwithstanding this advice it is not uncommon for me to receive letters from parties north, stating that they have sold their real estate, packed their household goods and bees into cars, and are to start for this State within a day or two. Such people seldom have their expectations fulfilled, and yet I am blamed for their blunders and lack of judgment.

The object of this article is to say to all, Do not do this. At any time it is a dangerous experiment, and at this particular time it is almost sure to bring disaster. We have just passed through the coldest spell of weather that the writer or any of his acquaintances have yet seen in Florida. Fifty-one years ago there was a similar freeze, a little later in the season, and perhaps the mercury took a little lower dip, that killed all of the mangrove and orange trees throughout the northern half of the State. This has doubtless killed a large part of the mangrove, but just how much can not be told as yet. Messrs. O. O. Poppleton and Jesse Oren, of Iowa, both well known to the readers of your journal, and myself, went out to some of the islands in the river during the last day of the cold snap, to see what the effect had been, and, to the best of our combined judgment, about four-fifths of the mangrove was destroyed. This being the case, the bee-keepers of this section can not expect a large crop of honey this season; and whether or not the next two or three years will give much better crops, will depend on whether or not the roots are killed as well as the stock. How far south of here the devastation extends, I am not able as yet to say; but as Mr. R. S. Sheldon, of New Smyrna, intends to start south this week to find a location for his bees after the early bloom is over here, we shall probably know after a while.

Our oranges are all frozen that were left on the trees; but although the mercury went down to 20° above zero, the trees appear to have come through all right in this section. The cold spell has destroyed a good deal of property, and proved to be a very serious matter with many; but it neither caused loss of life or destroyed buildings, as blizzards and earthquakes do, and is much less likely to recur than either of them would be in countries subject to them. I accept it as a part of the programme of life, and shall go on with more confidence in this country for orange-growing and bee-keeping than ever before. W. S. HART.

Hawk's Park, Fla., Jan. 18, 1886.

Friend Hart, I thank you for your caution to the people who get the Florida fever, or any other fever, and pull up stakes, take family, bees, and all, and start, before the head of the family has even gone ahead to reconnoiter the ground. Some of you may remember our friend Damkohler, who wrote with such enthusiasm—see GLEANINGS for 1883, p. 377. Well, a letter is just at hand mentioning his wife's death, and that he is alone with an infant and a family of small children, himself worn out with fatigue, and almost ready to give up, away off in the wilds of Florida.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from Jan. 15.

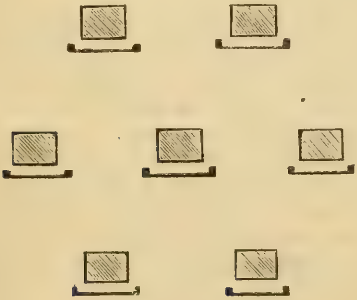
CHAPTER IX.

He which soweth sparingly shall reap also sparingly.—II. COR. 9:6.

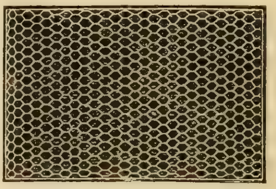
The above text does not, perhaps, cover the ground of this chapter, but it comes nearer to it than any thing else that now occurs to me. The point I wish to touch on in this chapter is this: After having once prepared our ground nicely for a crop, we want to be sure the crop is put on to it. In our best books on market gardening we are told how many plants can be put on an acre. For instance, Landreth's earliest cabbage is so small and compact that 15,000 may be grown on an acre. Now, real nice fine specimens, started in a hot-bed or greenhouse, so as to produce heads in June, ought to bring 10 cents a head. This would make $1500 for an acre of cabbages. If these figures are too large we will suppose they will bring 5 cents a head, which will be $750 per acre. Last June we got 20 cents a head for all the early cabbages we had to spare, which would be $3000 per acre, providing we had a market that would take the whole of an acre. Now, what is the trouble with these figures? Why, the trouble is this: 15,000 heads *could* be grown on an acre, providing every inch of the ground were brought up to the highest fertility, and providing, also, that the plants were set at mathematically correct distances; that is, each plant should be just so far from its neighbor, and no further, and there should be no vacancies. This last matter of vacancies is what I wish to speak of now. Farmers, gardeners, and almost every one who works in the soil—from those who get a dollar for the product of a square yard in the greenhouse, to those who get only a few dollars an acre from their crops out on their farms, all waste time and money by not having their ground thoroughly and *accurately* seeded. What I mean by "accurately" is, that just the right number of plants are put upon an acre—no vacancies, no crowding, and no getting too far apart. It seems to me there is no tool on the farm that is so far behind the times as the marker. The seed-sowers do better, but it seems to me that these can be greatly improved. With the wire-check row, and careful management, there is a pretty good prospect for a full crop; that is, for about all the ground will do; but to go over our farms as we ordinarily find them, my opinion is, that, in this matter of seeding alone, it is a common thing to lose half the crop.

TRANSPLANTING.

Now, if this matter of preparing the ground nicely—manuring it and all, and then not getting a crop on it because a plant has not been made to grow where the ground was ready for a plant, is expensive business, it is still more expensive to prepare ground for a greenhouse, and go to the expense of glass to put over it, and steam-pipes and fuel to keep it warm, and then not have every square inch occupied, not only every day, but *every hour*, with some sort of a plant. During the convention of the bee-keepers of our nation at Detroit, Dec. 9, 1885, I started out in the morning to visit the greenhouses in the suburbs; and one point I wished to determine was, whether the proprietors kept their ground all doing something. I found they didn't, by any means. At one place where lettuce was bringing $2.00 a bushel, a crop had been taken off, and the ground was lying idle, while plants that sadly needed more room were standing in a bed near by. The man in charge was standing around, smoking his pipe, saying he knew the plants ought to be in that ground, but he hadn't got around to it. Now, *I* should want to see the ground nicely fitted, and more plants growing, in the place of those taken out, within *one hour;* and under such circumstances I would take up the young plants with a good ball of dirt hanging to the roots of each, so that there should be no stoppage in the growth—in fact, take *all* the earth to a depth of one or two inches, along with the little plants when they are taken up. Then they have no check, but find themselves already growing, spread apart so the leaves that have been struggling for light and air can, any of them, have a nice little space to fill up with nice crisp foliage; and not only did these men let the ground lie idle while the December sun was pouring down through the icy sash, but when they planted them out they did it in such a slipshod way that some of the little plants had nearly a foot of room, and others, perhaps, not six inches. I would have decided just how much room I wanted for lettuce-plants to occupy, and then, in view of the expense of the space it occupied, I would have them at exact distances. Do you say, "This mathematical accuracy is all very well to talk about, but it won't pay in practice"? Just wait a bit. I suppose most of my readers are familiar with the quincunx plan of planting fruit-trees and other things where we want to get as much room as possible for each plant, and still have the ground all covered. It is simply adopting the plan the bees use in building their cells. Where an orchard is planted with the trees in squares, there is quite a space in the center of each square, comparatively unoccupied. Fruit-growers sometimes put a peach-tree in this center. A much more economical way is the plan of which I have spoken. It is, to have each plant or tree the center of six, and the six are at exact distances from each other. The cut below, taken from our A B C book, will explain this, only that was made for bee-hives and grapevine trellises. You can suppose each hive to be a cabbage-plant. The cabbage-plant sends out its leaves, usually, in pretty nearly a circle. When they get so they crowd each other, these circles will so adapt themselves as to pretty nearly cover the ground; each one being squeezed a little against its neighbor, would give exactly the form of a cell of a honey-comb.



How shall we get our plants set like this without too much expense? Well, the plan of sowing things in drills, if the plants could be made to "break joints," as it were, would accomplish it; but even if they do not break joints, it is, I think, as a general thing, rather ahead of the hill system, unless, indeed, we have a wire-check rower to place the hills so they break joints exactly, and make a corn-field look like the above figure. Then I should want seed enough put in so that each hill can have exactly the right number of stalks and no more. There is probably no method of accomplishing this latter, except thinning. In setting out plants, however, we can do it just as well as not; in fact, with the little device figured below, and which is, so far as I know, my own invention, we can do it *better* than not.



TRANSPLANTING-FRAME.

The above is made by stretching a piece of poultry-netting over a frame of half-inch iron. I would have this frame made of *iron* instead of *wood*, because iron, by its weight, stays right where it is laid, and is not easily moved around, even if you hit it with your hand while transplanting. You see, if you should give it a hitch after a part of your plants are put in, it might be difficult to get it back into its place again, and this would spoil the symmetry of your rows. In use it will pay, perhaps, to have two sizes of these frames. One of them is two feet wide, and just long enough to lay inside the side-boards of the benches in our greenhouse. The other just drops inside the boxes we pictured on page 60.

Now, then, when your seedlings, such as we told you how to grow in the chapter before this, have got so far as to show the third leaf, and begin to look somewhat crowded, take them up with the fibrous moss, or peat, I have described, adhering to the little rootlets, and plant each one in the center of one of the meshes of the frame. Our method of transplanting is to take a little wooden stick, the size of a lead-pencil, or a little larger. Instead of having the end of the stick a sharp point, however, let it be flattened so as to be perhaps a fourth of an inch wide at the point. Lay the plant in the center of one of the meshes, and with this flattened point of wood push it clear down to the first leaves, then with the same stick press the soil around it. When you finish the box, take a watering-pot with fine a rose and soak the soil so as to have it settle all about the little rootlets. If you do your work well, not one in the box should fail. The soil to be put in these boxes to start the little plants, should be much like that prepared for the seeds. An inch of fine old manure in the bottom of the box will be quite a help. When they get too much crowded, plant them out in the same way in larger boxes, or in the open ground. By this time, take every other mesh of the transplanting-frame, and, if you choose, every other row in the meshes, according to the size of the plants and their habits.

We work in this way, cabbage, cauliflower, kale, lettuce, celery, and tomatoes. You will see, we have absolute mathematical regularity, and with no waste ground. When the weather is suitable to work in the open air, use the same frame there. But I would have all my plant-beds, outdoors as well as in the greenhouse, made of very deep rich soil; and if it is soil that will bake over, put on enough peat to cover the surface—at least, to do entirely away with baking. We can not tolerate a hard crust around our plants, nor over our seeds. Your plants will be all the better and all the stronger if they are transplanted *twice* before they are put out in the field.

Some may ask. "Why this laborious transplanting?" Several things are accomplished by it. First, we get a stronger fibrous root than can be secured well otherwise. Second, we economize space. In one of the boxes I have described, you can keep about 2000 little plants until they are two or three weeks old. When transplanted by the frame, these same boxes will hold about 140 plants each. They can stand in this box until they are ready to go into the open ground, as a rule. With celery, and some other plants having a great mass of fibrous roots, we can, when the time comes to transplant for the field, turn out the contents into one fibrous sod of matted roots and soil. This sod may be handled as you would handle a door-mat. Lay it on a smooth board (such as a hive-cover, for instance), and take a long butcher-knife and slice the plants up into little squares—or, rather, little hexagons. Each one looks like a potted strawberry-plant, and you can plant it out in good soil, and have it grow without a single failure of a plant, or any check, by transplanting. The White-Plume celery that we have been selling for six months at such good prices was all raised and transplanted in this way. A good hand will transplant 500 seedlings into boxes in an hour; and where the soil is just right, he can put nearly as many in the open ground; so you see that transplanting is not such very expensive business, after all. In the greenhouse, you have your box on a table of the right height, so it is not nearly as fatiguing as working on your knees in the open air.

The third reason in favor of transplanting over sowing the seed is, that in transplanting you get the plant where it ought to be, and no failures; whereas, if you sow the seed this would be next to impossible, without a very expensive thinning-out. Last, but not least, we get our plants large and strongly rooted, in full vigor, and ready to go into the ground the very day some other crop has been marketed and sold. We also have the plant prepared to take right hold on the manure—that is, you need not purchase your manure, if you have to buy it, until the plants are ready to take right hold of it. You see, you have the use of your money longer.

FILLING IN WHERE PART OF A CROP HAS FAILED.

For a good many years I have been in the habit of planting over where the seeds did not come up. Sometimes we plant corn again where a hill has failed; at other times we put in a cabbage or tomato plant. Later in the season, white beans, etc. Now, I have come to the conclusion lately, that I want no more mixing up, if it can possibly be avoided. Suppose we have an order for green corn, when the crop is about exhausted. I tell the boys they can get some nice corn by hunting up the hills that are planted a second time; but the job of hunting is more than the corn is worth. Going over the field for here and there a few tomatoes, is about as bad; and even going over the farm to gather the white beans that have been put in waste places is a good deal the same way. The boy who is sent gets only about half of them. I tell him to go out again, and then find a lot missed. I want, if possible, the whole ground occupied with one crop, and I want that crop to ripen all at once, as far as possible. When it is all ripe, I want to be able to clean the ground and prepare it for another crop, and so on; and in no other way can this be done so well as by transplanting—that is, such plants as are usually worked in that way. Last season I transplanted corn and cucumbers, and made a success of it too. In this way I had no vacant hills, and yet my plants were all of one age. With the cucumbers we dug a good-sized hole, then divided the hill with a spade while another hand with a shovel cut under so as to take a large shovelful of dirt, plants and all. Scarcely one of the transplanted hills wilted where it was done carefully. Of course, this will pay only with crops such as market gardeners raise.

CHAPTER X.

By wisdom is a house builded.—PROV. 24:3.

Well, friends, very likely we shall need a deal of wisdom in building some sort of a structure to keep the frosts of March and April away from our little boxes of plants, even if we don't have very many of them, nor need very much of a protection. Your plants are taken up from the seed-bed where they grew, and planted two inches apart, according to our directions in the last chapter; and the next thing that comes up is, "Where shall we put the boxes?" If you have plenty of windows opening into a warm room, they can be set around the windows or in front of them; that is, a certain number of boxes can, and they will do this way tolerably well until warm days come so you can put them out. Of course, you must turn one side and then the other to the light, to make them grow straight up. If you get them very far from the window, you will find that, in their efforts to get to the light, they will not only tip over sidewise, but they will stretch their necks, as it were, and thus get long-legged, or "drawn," as gardeners call it. Well, suppose the windows do not answer for the quantity of plants you have got nicely started, what then? Why, you must put them outdoors in a hot-bed or cold frame; and in making even a simple structure like this, we want to scrape up all the knowledge we have gained in regard to heat, light, ventilation, etc. Our cold frame or hot-bed must first have a sunny place—a southern slope; that is, a piece of ground sloping slightly to the south is what we want. Next we want to protect it from the winds by tall buildings, if we can get such a place; but if not, a tall board fence, or something of that sort. High hills and overhanging rocks are, of course, better than buildings or any thing else, if you can get them. Have the tall buildings, overhanging rocks, or high fences, on the north and west, if possible. A similar protection on the east will make it still better, so you see a gully fronting south between two hills would be about the thing. Of course, you want a protection on the north to keep the north winds from coming down this gully. A building would probably be the best thing. I used to think, that *under* an overhanging rock, or under a shed, would be just the place—the shed, of course, fronting the south. The objections to a shed are, that it cuts off the light, making the plants have a tendency to turn off southward, and stretch themselves up, as I said above. From this, we see that, whatever covering we have, it must be glass so as to admit light. Even the north roof, that the sun never shines through, must be transparent, to get the best results.

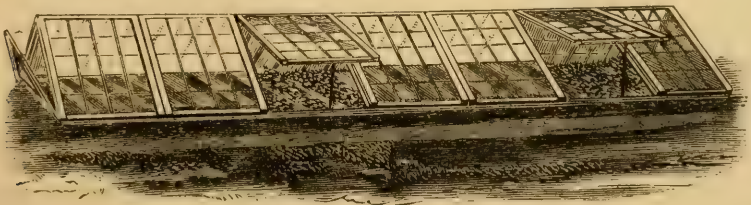
Having chosen our location, we will consider the simplest form of a plant-bed. The smallest size usually made is that of a hot-bed sash, generally 3 x 6 feet. In order to avail ourselves of the heat of Mother Earth, we will dig down, say, 18 inches into the ground. To keep the dirt from caving in upon us, put in a wooden box 3 ft. 1 inch by 6 ft. 1 inch, say, outside measure. The sides of the box may be, say, a foot high. If the ground is frozen when you commence, you will have to chop it out with a pick or an old ax. When you get some fine dirt, bank it up around your pit, but let the bank be at such an angle that it shall not prevent any of the sunshine going clear to the bottom of the pit. These directions are for the *south* side; but if you have a slope around the other sides about the same, it will be all right. After you get it dug, put on your sash and wait until the sun shines enough to thaw out the interior by going through the glass. If the sash is placed at an angle so that it faces the south, it will heat faster, but this is not very material. The large cold frames and hot-beds, at Jersey City, near the city of New York, have the sides almost level. Perhaps the south side is an inch lower than the other—may be two inches, but the slope is so little that I could hardly notice it. They used plank for their supports to the sash, and the plank were planed on top so as to be perfectly level, so the sash shuts down as nearly air-tight as possible. When a sunny day comes, so that the ground is thawed up inside, you can remove your sash and put in boxes of plants. Now, then, you are to watch them and take off the sash whenever it is not freezing weather outside. Sometimes a cold wind will harm the plants when it does not freeze. In such cases, keep on the sash, tilting it up a little to prevent the plants from getting too hot. The temperature inside is best not lower than 40°. Peter Henderson gives the rule for lettuce, cabbage-plants, radishes, etc., as 50° at night and 70° in the daytime; so when your thermometer shows 70° you want to be on hand and tilt your sash. If the sun is shining, and it is not freezing outside, take the sash off entirely. The clear rays of the sun, without any sash at all, are always better, if the plants do not get too cold. If unusually severe weather should occur, and continue for some time, you will need to put a shutter or straw mat over your sash. If that does not do, cover the joints with coarse stable manure—straw or litter of any kind. Leave this on until the weather moderates, and then gradually take it off. After your plants have become a little used to frost and cold air, after being taken out of the house, they will stand quite a freeze without injury; that is, even if the ground should be frozen over the surface, you will find the plants will come out all right. In fact, what are called cold-frame cabbage-plants are raised in the fall, and wintered over without injury, even where the thermometer goes down to fifteen or twenty degrees below zero.

As a rule, there is very little if any growth with any of these plants while the temperature is 40° or lower. Some plants will make some growth at 45°, and others will make a slow growth right along at 50°. Plants that are accustomed to grow at 50° become very hardy, and will stand severe freezes without injury. When it comes time to raise tomato-plants, peppers, and other tender vegetables, you will need what is called a hot-bed. This is simply a cold frame, just such as I have described above, with the addition of heat obtained from stable manure placed underneath the plants. Get stable manure that has begun to heat, or while it is hot. Fork it over and break it up fine, then put from one to two feet in your pit, under the boxes of plants. This will give heat enough to start seeds, even in the month of February, in our locality; but the cold frame will also start seeds without much trouble, in the month of March, say during ordinary seasons.

If you want a larger cold frame, of course all you have to do is to use more sash. In the figure below, we show you one we use with great satisfaction, composed of fourteen 3x6 sash. The sash is called 3x6, but it really measures 3 feet and 4 inches in width, from outside to outside.

Its location is on a level piece of ground, with our factory buildings on the north and east side. On the west we put up a tight board fence seven feet high. The outside of the frame is simply 2-inch joists about six inches wide, set up edgewise, and held in place by oak stakes two inches square, driven in perhaps two feet. We used about five stakes on a side. The inclosure is 11x23½ feet. Inside, the ground is made rich to a depth of perhaps 18 inches, with stable manure, peat from the swamp, and good rich soil. We found it not only laborious business to handle so many sash, but somehow or other, every time the sash were taken off and put back again, more or less glass was broken. It occurred to me that some arrangement might be made, obviating the necessity of taking off the sash; and at this date, Feb. 10, it seems as if my plans were a perfect success. The cold frame is full of beautiful cabbage, cauliflower, and lettuce plants, and not a plant has died. Shall I tell you how I manage it? You will notice the gable end is made like a door, hinged at the bottom, so it tips back. Well, when it gets too hot inside we open the doors at each end. This lets a draft of air right through; and even during very hot days the draft keeps the plants cool enough, even though the sash are all left in their places.

Of course, there must be some kind of a ridge-pole to support the sash at the top, and this is simply a strip of ⅞ board about 4 inches wide, supported by rafters made of pieces ripped from a two-inch plank. These pieces are about 2½ inches wide, set up edgewise. This makes the rafters 2 x 2½ inches, and the stout oak stakes driven into the ground prevent them from spreading. When in place, each sash laps one inch on to a rafter. Well, we found by trial that a heavy wind would blow the sash over and break the glass. To prevent this, we attach each pair of sashes to each other at the top, by a hook and staple made of galvanized iron. This allows them to be quickly moved and quickly fastened when put back in place. It

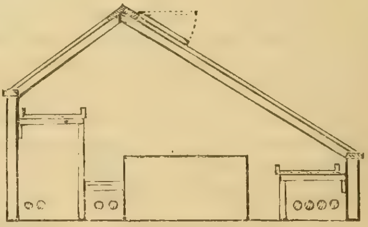


A COLD-FRAME FOR WINTERING OVER CABBAGE, CAULIFLOWER, LETTUCE, ETC.

also allows the sash to be tilted up, as shown in the engraving. We tilt them up to get out or put in plants, or give them water. When you have much sunshine, the beds will get very dry, and they must be watered, either with a sprinkler or a fountain pump; or you can pour water on, by being careful so as not to wash the plants out of place. However you do it, wait until they begin to show they are needing water, and then give the beds a good soaking. The very best way in the world is to take the sash off whenever there comes a rain. Whenever it is raining in the winter, and not freezing, the sash ought to be off. It is, however, less trouble to water the plants by hand, many times, than to take off the sash. We were annoyed last fall by the cats getting in nights, when the end-boards were left open, and scratching in the soft mellow earth. We stopped this, however, by covering the gable ends with poultry-netting, put on in such a way that the doors could be opened and closed without trouble.

Perhaps you may want to know what advantage cold-frame plants possess over plants raised in the house or in the greenhouse. As a rule, they are much stronger and hardier. As an illustration, we are today, Feb. 10, planting cold-frame cabbage and lettuce in the open ground. They have been greatly hardened, until they will stand almost zero weather without being injured in the least; whereas a plant raised in the greenhouse, without this hardening process, would be killed out with a freeze of 15 or 20 degrees. Plants may be raised in the greenhouse in February, and hardened by opening the cold frame, and exposing them gradually.

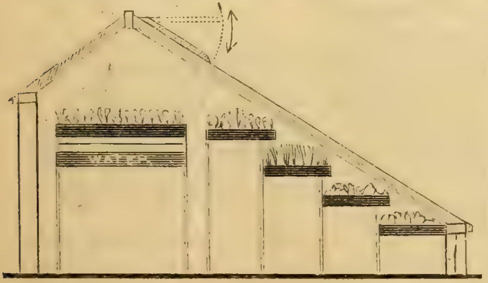
Now, it may occur to you that the cold frame just described could be very easily made into a very pretty little greenhouse. So it can, and our first greenhouse was made in that way. Just build the structure so one end comes up against a cellar window to your dwelling-house, and you have it. Cut the window down low enough so it will do for a door, then make a ditch or trench through the center of the building, 18 inches wide and about 3 feet deep. You can then walk easily under the ridge-pole, and you will have beds about the right width. If your walk is two feet wide it will be handier to get by another person, but it wastes your precious ground inside of the glass structure. Now, if you want to make the plants grow all winter you will need a little fire heat. The way we did it was by having a large barrel of water at the end of the cold frame, opposite the door. A steam-pipe went up one side of the path to the barrel of water, and down the other. When a cold night comes, heat the water in the barrel, by means of the steam-pipe, up to about the boiling-point, and it will keep your greenhouse free from frost all night. The evaporation of water from the barrel soon coats the inside of the sash with half an inch or more of frost, and this frost also closes all cracks and crevices with ice, so as to make the room air-tight during a severe freeze. You can have the surface of the ground for your beds, or you can have boxes, such as I pictured in Chapter VIII. The boxes are handier, because you can carry them with the plants right where you want to put the plants out. But, suppose your business demands a larger greenhouse than this cold-frame arrangement. Well, you can make it longer, or place another, just like it, right by its side. The latter plan has been the one advised until within a few years. Peter Henderson, however, of late uses a structure something like the figure shown below.



HENDERSON'S NEW METHOD OF BUILDING GREENHOUSES.

This building has one long side of sash, facing the south, as you will notice. This long side is about three times the width of the sash, on the north side. For instance, if you use six-ft. sash on the north side, you will want rafters about 18 feet long on the south. This makes the north wall a good deal higher than the south wall. One would naturally suppose that these walls should be made of brick or stone; but Mr. Henderson states, and I think he is right, that a wall made of cedar posts, covered with rough boards, so as to inclose an air-space, is more effective and more substantial than brick or stone. To make it still more impervious to frost, there should be a tight covering of common tarred building-paper between the two board walls. We use matched ceiling for the inside, and drop-siding for the outside; tack building-paper on to the studding before the siding is put on. Where the building-paper is spliced, a strip of wood should be nailed across the joint, so that no cold air can get through anywhere. The interior of the house shows three benches for plants, and two walks. The first, or south bench, is the lowest of all; the middle one a little higher still. You will notice, that under the lowest bench are four steam-pipes for heating purposes. Two more are seen under the walk, next to the tall bench, and two more under this bench. It seems a little strange, but it is nevertheless true, that the coldest place is to the south side, over the low bench.

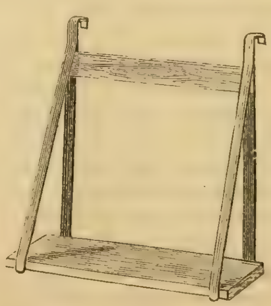
Now, it is laid down in our works on greenhouses that plants do better, the nearer you get them to the glass. To take advantage of this, Mr. Henderson, in his new style of house, raises them as he goes back. I knew this was a fact, but I didn't know until the present winter that it made such a very great difference. Almost every box in our greenhouse seems to indicate, as plainly as words could tell it, that they want to be close to the glass. One of the standard works on greenhouses says no one has yet ever been able to explain *why* this is so. Plants away from the glass keep reaching up and growing long-legged, as I have told you; whereas, when they are close up to the glass they seem satisfied; they put on a dark rich color, and grow stocky and short, the way we want them to. To test the matter thoroughly, we tried boxes in different positions, and rigged one of our greenhouses so as to be pretty much like the figure shown below.



PLAN OF A GREENHOUSE, AS PREFERRED BY THE AUTHOR OF THIS BOOK.

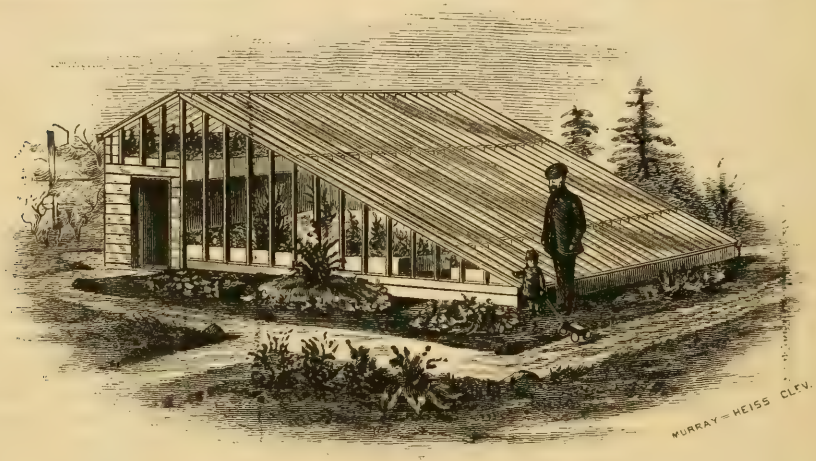
You will notice in the above, that the first bed is much like Henderson's. It is, however, to be only 2½ feet from the ground, the south edge coming close to the glass, just allowing the plants room to grow. The next bed is just two feet higher up; and if you call the thickness of a bed six inches, this upper one is just four feet from the ground or floor, obliging one to stoop over when he wishes to get at the lower bed. As he has, however, 18 inches of space between the upper bed and the lower one, he can work very conveniently with his head bent over, as it would naturally come while working in the lower bed. The third bed comes two feet higher than the second; the fourth about two feet higher than this, which would bring this last, and also the center bed, with its upper surface, 7½ feet from the ground.

The supports for these beds may be straight-grained pine or ash, or, better still, gas-piping, for we want just as little shade as possible. Every thing should be painted white —rafters, supports, sides of the beds—in order to make the room as light as possible. Under the large bed in the center we have a water-tank. This tank is to equalize the temperature of the building, and to furnish water for watering plants. A hose attached will sprinkle the three lower beds easily and expeditiously. Whether the building is warmed by steam, hot water, or a flue, I would arrange it so as to heat this body of water on very cold nights. The water may be procured from the roof partly; and, if steam is used, from the condensation of the steam. The roof is all permanent, except the hinged sash shown, for giving ventilation. The ventilating sashes should be placed about three feet apart—they may be 3 x 4 feet in size; but be sure to have them lap *over* the other sash, not to go down between them. When they get covered with ice, you will know why. In regard to the width of the beds, we have decided on about 3½ feet. The operator can work handily this distance, if he is just the right height from the surface of the bed. To get this height, and have it always just the same, and still not be cumbered with elevated walks, we use an invention of my own, figured below.



MOVABLE STEP TO HANG ON THE SIDE OF THE ELEVATED BEDS.

An explanation is hardly needed. The board is 3 ft. long, 6 in. wide, and ⅞ thick; the irons can be made by any blacksmith. For a man 5 ft. 8 in. high, the distance from the hooks to the surface of the step should be about 2½ ft. You can get the most convenient height for reaching and working across a bed 3½ feet wide by blocking up a plank until you get it just where you want it. The center bed is 7 feet wide, so you can stand on either side. I would have 18 inches between the center bed and the wall, and between the two upper beds. The building may be of any length you choose. I would suggest not less than 25 feet. Below is the cut of our own greenhouse made last fall.



MURRAY = HEISS CLEV.

OUR GREENHOUSE, FOR RAISING LETTUCE, RADISHES, CELERY-PLANTS, CABBAGE-PLANTS, ETC.

This building was put up last fall, and the work was all done by our own hands, and it has answered the purpose perfectly, in every respect. The cost was perhaps from $150 to $200, counting every thing. It will be noticed that the arrangement of the beds is not exactly as I have recommended; but by careful experiment on a smaller house attached to the above, I am satisfied the plan laid down here is the correct one. Our heating is done by steam pipes, a three-inch pipe going clear around the outside of the room, and terminating in a large cistern directly under the large central bed. With the water in the cistern heated up nearly to the boiling-point, the temperature of the room keeps perfectly, even when the temperature is zero outside. The dimensions of the greenhouse pictured above are about 20 x 24 ft.

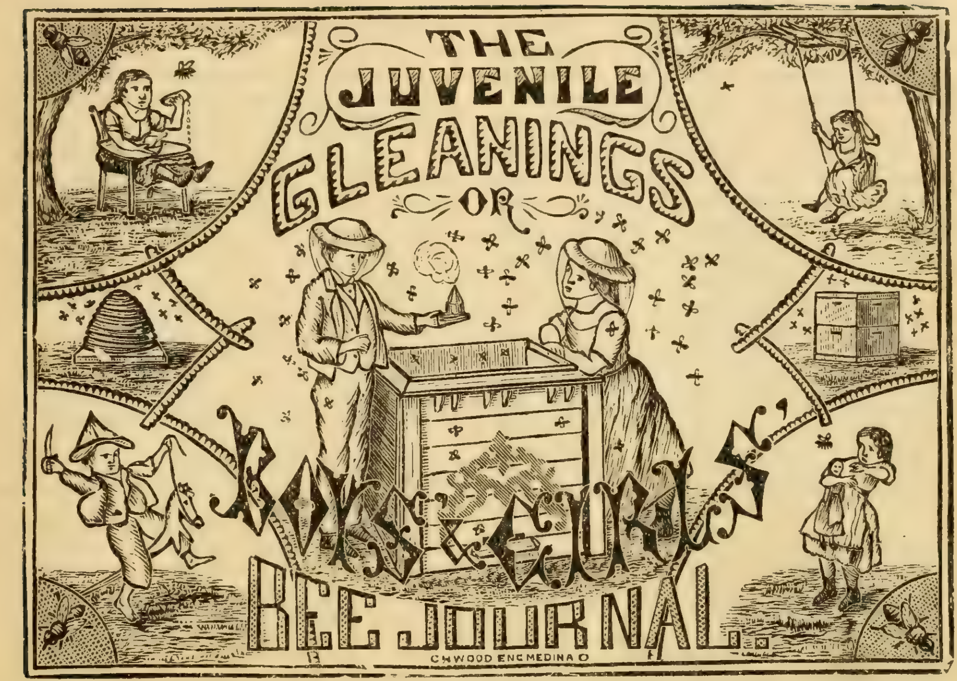
In the above directions I have considered glass only as a covering for the cold frames, hot-beds, etc. In Peter Henderson's latest catalogue he mentions the use of oiled muslin in place of glass, and states that it is superior to glass in respect to injuring plants by *too much* heat. As the oiled muslin is only partially transparent, of course it won't heat up as glass does. Perhaps we might mention here that the heat of the sun, when confined in a close box, covered with a sheet of glass, will give heat sufficient to melt beeswax, and scorch wood. In an experiment made this 11th day of February, with what bee-keepers call a solar wax-extractor, the thermometer indicated a heat of 180°. Well, the muslin, being somewhat porous, allows a slow circulation of air, besides obstructing a great part of the heat, and yet it is a tolerably good security against frost.

We take the following from Henderson's price list, although we have not had an opportunity to verify the statement by our own experience:

> This we have found an excellent substitute for glass, in protecting and forwarding all kinds of seeds and plants for which glass sashes are used in early spring. It is safer, in fact, than glass, as it protects at night, while the temperature is not raised too high by day, as is the case with glass sashes, unless great care is given in ventilating. And being light and portable, it can be sent into sections where it would be difficult to get sashes. Moreover, it costs only one-eighth the price of glazed sash; and as it is waterproof, with care will last for ten years.

The fabric above is nothing more than common cheese-cloth, coated with boiled linseed oil. It is, however, so easily torn or injured that we are going to test by its side some stout cotton cloth, oiled in the same way. A large sheet of this material could be easily handled by two men, and might save many times its cost during a single night, when late frost occurs unexpectedly. For such a purpose it might be supported by some stakes stuck down among the plants, or by some long light strips of pine, with iron stakes attached, so they can be easily and quickly pushed into the ground.

To be continued March 15.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

White Lumber for Making Sections.

RAISING BASSWOODS, AND SOME OTHER MATTERS PERTAINING THERETO.

Cast thy bread upon the waters: for thou shalt find it after many days.—ECC. 11:1.

THE question is being constantly agitated at our conventions and through our journals, in regard to cutting down our basswood-trees that furnish the honey to make nice white sections to contain said honey, and present it to consumers in a marketable shape. The question has been asked, "What shall we do to stop it?" *My* answer is, "Raise more basswoods to take the place of those being cut off." It looks at present as if there were no other lumber in the world equal to basswood for this purpose; and if such is the case, why not start basswood-forests at once? These trees, while getting to be of a size suitable for honey-boxes, will furnish millions of pounds of honey, so that we have some bearing a crop while others are making their growth for timber; and, it is my honest conviction, that they will pay their way right along. We want men and boys with brains enough and energy enough (which is sometimes more needed than brains), to go to work and gather the basswood seeds, or put out the cuttings, whichever may be best, and start the trees growing by the millions. They can get their money back as they go along, by selling the little trees to bee-keepers, and others who want them. If little basswood-trees were now in the market, say two or three inches high, or of such size that they could be sent cheaply by mail, and offered at a price as low as other forest-trees are offered, millions of them could be sold, and at a good profit too. Then we want a little treatise on basswood-growing, by some one who has actually done it. We want to know exactly the conditions they require to make the wonderful growths that we often see them make in their native forests. We want to know just how to make them boom. If it is necessary to bring in father Cole's agriculture, it will pay us to go to the expense of that. And, by the way, I am going to have some little basswood-trees put right over my reservoirs. I want to see the little bundles of fibrous roots just revel amid those piles of stone, covered with water the year round. We want big, strong, thrifty plants to start with—something like the best plants we get of market gardeners. In my own basswood-orchard there are now many trees that bear pretty fair crops of honey, and they would make quite a nice lot of beautiful sections, if they were to be cut down. One big mistake I made was in putting the trees too far apart. The largest trees in the whole plantation are where I set a lot of trees left after we got through, and these large trees are standing now not more than a yard apart. If put in rows twelve feet apart, and six feet apart in the row, they could stand there until the larger ones would make quite a lot of beautiful white sections. It seems pretty hard, I know, to talk about cutting down a strong thrifty tree while in full bearing; but, dear friends, can't we raise enough of them so they can be spared as well as not? The loss of this source of honey is more to be feared by the bee-keepers of America than the craze about artificial honey-comb, or, in fact, any other craze that may come up. Farmers *will* cut down basswoods, where a good price is offered for the lumber, in spite of any thing we can do.

Now, then, let us gird up our loins and commence raising trees. The little trees we pick out of the forests are not first class. They need planting out in good rich nursery ground for a year or two before they are fit to sell; and my impression is, we could get nicer trees, quicker and cheaper, by raising them from the seed in the first place. Has anybody any basswood seed that will grow or can it be had? Has anybody any little trees raised from the seed, that they will send at reasonable prices? Those pulled up in the woods are almost always twisted and starved-looking. We want some nice ones to start with. Rouse up, ye juveniles, and help your Uncle Amos in his plan of providing basswood honey for future generations. Why, when I think of it I almost feel as if God had a promise laid away somewhere, that we haven't found yet, that those who labor for new generations, to rise up long after them, should somehow be permitted either to be present or look on and see the fruit of their labor. I do not know what will be going on in 1900; but somehow I feel as if God were going to give me a glimpse of it, and allow me to love the bee-friends and their children's children then as I do now.

Now, then, boys, hurrah for the young basswoods! not only during the year 1900, but during this bright new year of 1886. How much can we do toward it? If we can not get seeds, let us get nice little trees from the woods. Give them poultry manure, give them ashes, give them bone dust or phosphate, or whatever they tell us they like, after we have offered it to them. I have seen them take bone dust and ashes already. When you see their beautiful green leaves unfolding and spreading out, of prodigious size, even though they are not yet a foot high, see if you do not say with me they are one of the prettiest plants that God ever put on this green earth; and they are the plants that are going to furnish the beautiful white delicate aromatic comb honey that no man ever counterfeited successfully yet, nor ever will, while this green earth shall last.

Ernest just now reminds me that I ought to have made the above to occupy the space assigned to Myself and My Neighbors, and I think it will have to do, even though it was not intended for it. You who go into this little basswood-tree business are to be my neighbors; and I confess I should like to call the little trees my neighbors as well. How can we have pleasanter "neighbors" than a row of beautiful basswood shade-trees in front of our homes, or, if you choose, clear around our farms, or wherever there is a roadside? Wait until about the fourth of July, when the trees are in full bloom, and roaring with bees, and then tell me if even one such a tree is not a neighbor worth having.

THE BEE'S STORY.

SOMETHING FOR THE "WEE" FOLKS.

LITTLE Millard, who attends the Bloomer school in a western city, was walking slowly home from school one beautiful summer evening. This little boy liked nice flowers, and knowing his mother would tell something about any flower he might bring her, he always watched for a flower. Right by his path lay a beautiful red rose.

"Oh, how pretty!" said Millard; "mamma will like that, I know she will."

When he stooped to pick it up, he heard a buzz; and, looking up, saw a bee very near his head.

"Nasty thing! I'll kill it; it shall not spoil my pretty rose," said he.

He began to throw stones at the innocent bee. Why did the bee not sting Millard? Did it not find the flower first? Of course, its right came first, but it is going to talk to Millard.

"If you will sit down, Millard, and take the rose in your hand, I will alight on it and tell you about my home," said the bee.

"Your home!" said Millard; "you have no home."

"Yes, I have," said the bee.

Timidly our Millard sat down, and the little brown coated worker took his seat on the rose.

"My story," said the bee, "must be short, for the flowers have more honey than we can gather to-day."

"What do you want honey for? Where do you put it?" began Millard, as fast as he could talk.

"Well, I will tell you all about my home. What I want honey for, and where we put it," said the bee. "As you go to school to-morrow," it went on to say, "look in Dr. Lutes' yard. You will see several little houses—boxes you will call them. I wish you could see inside. The one next the corner is my home. Our house is two stories high. In the first story, or down stairs, there are eight long narrow rooms. Here is where the baby-bees stay, each having a little cradle to himself. When a baby-bee is five or six days old, the nurse-bee seals up the top of his cradle. Here he sleeps until he is big enough to come out and work in the house. Our mother stays here too. Her name is Queen Bess. She always has the nicest things we bring home. I always take nice things to her."

"That's like me," said Millard; "I am going to give my mamma this rose."

"You are a good boy, then. You wanted to know about what I did with honey. We have many, many nice boxes, or cells; into these we put the honey. You know we must work hard, for flowers do not bloom all the time. It is almost sundown, so I must hurry. We must kill a lot of lazy drones to-night. They eat much, but are so very lazy they never work at all. It is not worth while for them to live."

"Oh!" said Millard, "I do want to see your home; but the other bees will sting me—I know they will."

"No," said the bee, "not if you do not harm them."

"The drones will," said Millard.

"Oh! my dear boy, a drone can not sting. He makes plenty of noise, but, like bragging people, that is all it amounts to. We are both staying here too long, Millard, I must go. We will talk some other day." Away flew the bee, leaving Millard all alone with his red rose.

"I am going right home and tell my mamma," Millard said, and away he ran.

Estell, Hayes Co., Neb. LUCILLE L.

SOME INTERESTING OBSERVATIONS.

Actual Experience of a Juvenile.

LOSS OF HONEY BY DISTURBING IRRITABLE COLONIES, ETC.

THE bees are wintering pretty well so far. They had their last flight Jan. 3d. Since then it has been very cloudy and cold. Our bees are mostly hybrids, but there is one swarm composed of pure Italians, and many pure Italian bees are among the hybrid colonies. In 1884 all of our bees were very gentle, seldom stinging any one. This year most of our bees were pretty gentle, but one or two swarms were somewhat cross. In the spring one weak colony was destroyed by robbing, and another was saved only by being removed a couple of miles. This (although hybrid bees) proved to be a very gentle colony. During the autumn and winter, while looking into the hive while feeding it, it received many disturbances, but I could never see that they had any tendency to wastefully consume their stores. To-day, on looking into them, the hive-door came open with a loud snap, but I could not see that the bees were much excited, nor did I see them dive into the cells, as bees that are liable to consume honey, when jarred, get into the habit of doing. The crossest swarm that we have is the only swarm that I ever saw fill themselves with honey when jarred. I find that bees are very easily disturbed in winter. I once disturbed a swarm by simply tramping on the frozen ground near the hive.

QUEEN-CELLS.

Last June a box-hive colony that had filled the hive with bees, brood, and honey, started queen-cells.. One of the cells was rapidly built up, and was nearly ready to seal, when, on looking into the hive one evening, I saw that the cell had been well-nigh torn to pieces, and through the openings I saw the queen-larva. The next morning the cell had been mended, but it was only half as large as before. It was then abandoned.

This was several days before the first swarm came out. Now, what caused the bees (for it must have been the bees, and not a young queen) to tear down the cell? Last summer we had an after-swarm come out that returned to the hive. While going back they were very cross. The next day they came out to stay.

In the autumn of 1884 the bees gathered a great deal of honey-dew from the maples; and as a great many of the bees around died during the winter the honey-dew probably had something to do with it. Last fall I did not see a single bee gathering honey-dew.

BEES FLYING HOME BEFORE A RAIN.

I often notice the queer way bees have of hurrying home from an approaching rain. They pour in by thousands, and in a few minutes all from the fields are safely in the hive. While coming in they have an excited, hurried manner, and make a deep scared-like sound. They do this when a cool damp wind is blowing, and the clouds threaten rain. But if a rain slowly and silently approaches, they will work away, even if it is raining.

DRONES OUT OF SEASON.

Last fall, during buckwheat bloom, one of our hives became so crowded with bees and brood that they started a queen-cell, and we were afraid that they would swarm. About a month after the bees had killed their drones, some drones again appeared in three swarms. In one they were immediately killed, and in the second remained but a short time. The third colony that had them was the one just mentioned, that started the queen-cell. In this colony they were soon killed, the drone-brood torn out, the cell deserted, and swarming was abandoned, although buckwheat continued blooming. I at first thought it strange that bees would allow drones to remain after the honey-flow, and in the fall; but they were not queenless, and I could not see that any thing was wrong.

Three or four years ago some men living near us saw bees and comb on the side of a tree. Thinking there might be honey inside, they cut it down; but, lo! there was only a bunch of bees and comb on the side of the tree. A large hollow was below them, filled with ants. Could the bees have chosen the hollow, and the ants caused them to leave it? Or perhaps they settled on the body and went to work as bees sometimes do on fences, etc.

CHARLIE L. GREENFIELD.

Somerville, Butler Co., O., Jan. 27, 1886.

Friend Charlie, I believe you are right in thinking that it makes a difference as to what the temper of the colony is, in regard to the loss of honey from disturbance, and therefore it is, without doubt, more profitable to keep good-tempered bees than vicious stinging hybrids. I have seen queen-cells torn open as if a rival queen had hatched out and afterward patched up by the bees, and a good queen to issue from them. I suppose the reason was, there must have been a difference of opinion as to what course was best in the hive—that is, if bees do have opinions, and it looks as if they do.—It has always been one of the most interesting sights to me to see bees come home at the approach of a thunder-cloud, and you may perhaps remember that I have several times written about it. Their instinct is sometimes, however, considerably at fault. You will notice they may be frightened by a cloud that does not come near us at all; and, again, they may none of them, apparently, notice a coming shower, and in consequence get pretty well drenched before they make the "home stretch."

BRANDING CATTLE IN CALIFORNIA.

A TALK TO THE JUVENILES, BY AUNT KATIE.

DEAR JUVENILES:—Did you ever hear of a "*rodeo*"? That is the Spanish name for a gathering-up of cattle. Once a year, owners of cattle have them all gathered together in large correls, and those which are not branded (marked with their owner's initial or mark), are so branded. You will wonder how they can be told apart, as the cattle are allowed to all run together pretty much. You see, when a calf has been allowed to run with its mamma ever since it was born, of course it will stick close to its mother's side; and as the mother has a brand, of course the calf is branded the same. Once in a while an animal will escape being branded until it is too old to tell whose it is, and any one then has a right to claim it, and for just that purpose there generally is a lot of sight-seers.

One day, when we had been in California about one year we heard that there would be a *rodeo* here at Los Alamos, and we came down to see it. We came down the Santa Ynez Cañon. The hills around us seemed to be alive with cattle and horsemen. It made me hold my breath to see how those riders would come rushing down the hillsides, often on the full run. Sometimes a horse would stumble into a gopher-hole, and over would go horse and rider, sometimes badly hurt, but more often only scratched by the rough brush. Up they would get and off they would go, may be to perform the same feat several times, before the cattle were all gathered in.

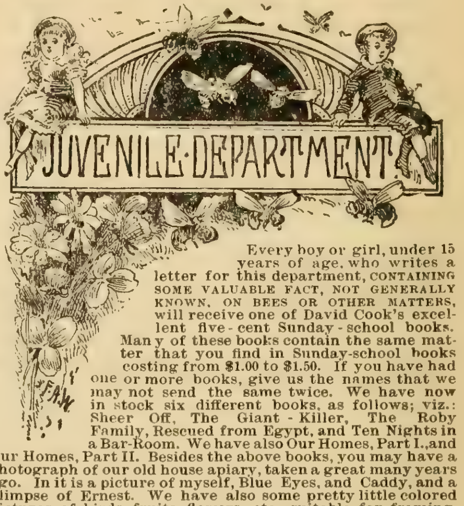
At that time many of the cattle were Mexican stock—long, lean-looking animals with tremendous horns; and if they found a person on foot they would kill him if possible; and even on horseback a person was not always safe. Many a horse has been killed, and the rider saved only by climbing a tree, of which there fortunately was plenty, or by some other strategy.

Well, they got all the cattle they could find on the ranches of the three men who had called the *rodeo*. There was a correl on the Laguna ranch, near a large laguna that the stockmen liked, on account of its nearness to water, and the cattle were within that correl. Such bawling and mooing! it was deafening. But the Spaniards there assembled seemed to enjoy it. Two or three had built a large fire, to heat the branding-irons in, and others were riding around, swinging their lassos, ready for the fray. Not liking to stay to see them work, I went on to a friend's house, while my husband stayed to see them, so I will give you his account of the way they did it.

As soon as the irons were hot, two Spaniards went into the correl on horseback, and one caught an animal by the horns with the lasso, while the other lassoed it by the hind feet. It is surprising how quick they can do it; and then each pulling in opposite directions, the animal would fall, and the owner's man would rush up with the hot iron and press it upon the fleshy part of the hip until it smoked. It seems cruel, but it is not worse than many a child gets burned. Then the lasso ropes are loosened, and the animal springs up and disappears in the band. Sometimes, if the victim was a steer, he would charge upon the horsemen. Then how the outsiders would shout and laugh! As it will not do to leave so many cattle together long, they have to work fast, so that changes are made frequently; and if any one is not expert, his time for brave show is short. After all are done, then a fine fat animal is slaughtered, and they gather around the fire with the meat cut into long strips with the grain, and roast it over the glowing coals on long sticks. Then they feast and tell stories, and generally make a night of it, as many have come miles to see the *rodeo*.

The glorious weather and dry ground make camping-out a delight. The next year after that *rodeo* was one of California's dry years, and the most of those cattle either starved to death or were slaughtered for their pelts, and these ranches were rented to American farmers, so that, for this part of California, the *rodeo* is a thing of the past.

Los Alamos, Cal. AUNT KATIE HILTON.

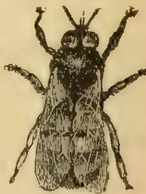


JUVENILE DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

LET me introduce you to our good friend Mr. Drone. He has had his picture taken, and, like all big bee-men, he must have it engraved. Don't you think it is a natural likeness of our old lazy friend? He is more clumsy and big-headed than the rest of his family, and, like barking dogs that never bite, he will make more buzzing than half a dozen bees, but never stings. His wings are large, and, for that reason, he can easily be picked off the combs. If you are to learn to cage bees, there is nothing better to practice on. As he can not hurt you, you need not feel at all alarmed; and if, by an awkward movement, you should maim him, it will not be a bee or a queen. After practicing upon him awhile you can then try a bee; when you learn the knack of putting bees into a cage successfully, without being nervous, you can try a queen. I tell you, little folks, it is a real art to pick up hundreds of bees and queens, day after day, and not maim one. If your father is a queen-breeder, see how useful you can make yourself to him. Now a few words about bees that have lost their stings.



Reports are coming in quite briskly from the juveniles, all showing invariably, so far, that bees, after the loss of the sting, die very soon; but, as has been said, all the experiments up to this time point to confinement of the injured bee. Some of the older folks have said that a bee, shut up alone on Good candy, would die any way, whether it had received any bodily injury or not. I suppose they mean that the little bee gets so lonesome and homesick that he would just die of grief. Now, hereafter, when a bee loses its sting, do not cage him alone, but cage him on Good candy, with other bees that are perfectly sound, so far as you know.

I have another problem, which is this: Cage a single bee, one that has not lost its sting, and see how long it will live. If he dies within 6 or 24 hours, or possibly at two days from time of caging, we shall then conclude that the loss of the sting in the experiments so far given did not necessarily kill the injured bees. If, on the contrary, a single bee will live four or five days, or even a week, caged alone, we shall infer that there has been something faulty in your work. My experiments so far lead me rather to the latter opinion. Those of you who are situated in the Northern States will have to wait till warmer weather; for, if a bee becomes chilled once or twice, he will not live long; but the little friends in the South can report for the next JUVENILE GLEANINGS.

A NEW FLY-TRAP.

I must not forget to mention our new improved fly-trap, and it is not patented either. What do you suppose it is? Why, it is Huber's chicken. There was only one that hatched in January, from the old hen that we promised to tell you about. As there was only one from the whole sitting, we took the old hen away and gave her another lot of eggs. No, sir! the old biddy absolutely refused to sit any more, so we put her back in the poultry-yard. The little chick is alone by himself in the greenhouse. In the daytime you just ought to see how he will hunt and eat those little green flies that are such a nuisance. His eyes have become wonderfully acute, and he will pick out a bug where you would almost say there wasn't any at all. Yes, he will travel up and down those beds, and, if you could see him, you would pronounce him a veritable living fly-trap and "bug-hunter." Huber has just gone down to see him, for the chicken likes company; and if left alone he will chirp as if calling the old hen.

ERNEST.

CAN WE TAKE CARE OF THE BEES WITHOUT PAPA?

Papa had 11 colonies of bees last spring. This fall we had 15 colonies in chaff hives, and mamma has sold two colonies. The snowstorm broke a peach limb and it came down on three hives of bees. My papa died Sept. 3, 1885. He was 37 years old. Do you think mamma, Harry, and I can attend to the bees? Papa took GLEANINGS. We like to read it.

LEE HOFFMAN, age 9.

Williamsport, Pa., Dec. 7, 1885.

We are sorry to hear of your misfortune, friend Lee. Yes, I feel pretty sure you can take care of the bees with the help of mamma. Our mammas can do wonderful things when they are obliged to, especially when they have several pairs of eager and willing little hands to help them.

ERNEST.

STARTING IN THE BEE-BUSINESS.

I will tell how I became a bee-keeper on my own account. I was riding through the pasture on horseback in September, when I found a swarm of bees on a crabapple-tree. I came home, and, pa not being at home, ma and cousin Willie went with me, and we shook them down into a Langstroth hive successfully, queen and all. When we got home we gave them one frame of brood and two frames of honey, and some empty comb for them to fill with sugar syrup. In a week or two a neighbor told pa she had a swarm of bees in an old house, and that if he would take off the weather-boarding, so she could get the honey, he might have the bees. He did so, and gave them to me. We put them in with those found in the pasture, after smoking them. The queen, ma put in a nucleus box with seventeen bees to experiment with, and she found that

MOTH WILL DESTROY GROWN BEES

as well as larvæ. She put them on top of the bookcase in the sitting-room. The air was warm and moist; and when she examined them in a few weeks, only the queen and five bees were alive. The bodies of the other bees could not be found. She cleaned up the combs, taking out every moth she could find, and tried again to see if the queen would not lay. She left them this time six weeks, then found all dead but some moths, fat and hearty.

We all study GLEANINGS and cousin Willie's A B C book, and like both very much. Our bees are packed in chaff, as you direct. I have one more heavy swarm that was a present to me in the fall. I hope I shall succeed, and be as industrious as the bee.

A JUVENILE.

Memphis, Mo., Jan. 14, 1886.

"TEN NIGHTS IN A BAR-ROOM," AND HOW TO DO GOOD.

I think my Ten Nights in a Bar-Room is very nice. I let several read it. Uncle Henry has sold nearly all of his honey. The weather has been so bad that I can not go to school. My uncle who was staying in Kansas has come back. He said he saw a town of prairie-dogs, wild-horse ponies, and antelopes.

VIRGIL PATTERSON, age 9.

Humboldt, Neb., Jan. 24, 1886.

Thank you, friend Virgil, for making so good use of the book we sent you. There is certainly a great need of more good temperance books in our homes, and Ten Nights in a Bar-Room gives a very vivid as well as true picture of the downward career of the drinking man. If your book has become too tattered to lend any more, let us know, and we will with pleasure send you another. Such acts of kindness may save some one from a terrible fate.

ERNEST.

WHAT DOES A BEE-STING LOOK LIKE?

My bee stung a piece of cloth, and I put it in a cage. It lived 45 hours and 18 minutes. I kept the sting, and it twitched for 12 minutes after it left the bee. I examined it under the microscope, and it made me think of a teapot with two spouts. From the looks of the bees we think their age has something to do with the time they live after they sting any thing.

GERTRUDE A. ORVIS, age 12.

Whitby, Ont., Jan. 11, 1886.

The two projections resembling spouts from a tea-pot were doubtless the lancets of a bee-sting which had been torn asunder. The sting proper is made of three little spears, nicely united together—one large spear and two small ones, or lancets. One sting that I once took from a bee kept wiggling for 20 minutes after. This illustrates the importance of removing the sting as soon as possible, as it will of itself work so deep in the flesh as not to be removed.

ERNEST.

ANOTHER BEE THAT LOST ITS STING.

Seeing that you had proposed to the juveniles the plan of removing the sting from a bee, to see how long it would live without a sting, I was pleased with the idea, so I tried it when pa was putting up bees to ship. One alighted on the smoker, and left its sting. I put it in a cage and gave it honey, and it lived only six hours and fifteen minutes.

Concord, Ky. **CLYDIE PURCELL**, age 13.

TURNING THE ENTRANCES OF HIVES TO THE NORTH TO PREVENT FLYING.

I play the violin. Do you love music? Pa had 17 stands of bees last spring, and lost one of them. He winters them in chaff hives on summer stands. He turns their entrances to the north, so they will not fly out so much when the sun shines, and the wind is chilly. They increased to 35 stands last summer, and made 466 lbs. of comb and 470 of extracted honey. Pa uses metal corners; he thinks they will pay for themselves in a short time. He takes GLEANINGS, and I like to read the juvenile letters. I don't work much at the bees, but pa keeps fancy poultry, and I help to take care of them. **WILLMER HORNING.**

Malvern, Ill., Jan. 10, 1886.

FLORIDA, AND THE EFFECT OF THE LATE FREEZE THERE.

I am going to tell you about the freeze we had down here. We had a very hard freeze. It killed all the oranges on the coast. There has not been such a freeze for fifty years. It killed the mangroves all down. You can go in the islands and see the big old trees all dead; they were killed by the great frost fifty years ago. I don't think that the bees will do much next summer, for the mangroves will not bloom this winter. The palmetto will be the only thing that they will have to get honey from. I don't think that any bees were killed by the cold. Our bees are all right now. We have no orange-grove, but I suppose we are just as well off, because the cold would have killed it. The oranges are all frozen, and good for nothing.

EVA S. GLAWSON.

Hawk's Park, Fla., Jan. 23, 1886.

DOES A NOISE INDUCE BEES TO CLUSTER?

I am going to tell you about our bees. This was a very poor season for honey, but still pa managed to get 700 lbs. of honey from 40 colonies, which increased to 50 by careful tending to keep down swarming, which our neighbor bee-keepers neglected, and they did not get any honey at all. Pa said he would like to see one of your Johnston pumps, and he would like to buy one if they would suit him. We take GLEANINGS, and all of us read it, and like it very much. I like to read the letters very much, and my sisters too. My little sister Lillie has to watch the bees in swarming time, and when they swarm she rattles a tin pan till pa comes to take them. Is it not funny how bees will settle at the rattling? They seem to like music.

CLARA LURKER.

Cold Spring, Ky., Dec. 21, 1885.

It *is* funny, Clara, especially if it is true, that noise induces bees to cluster. You will notice that the A B C book suggests that the noise drowns the shrill note uttered by the advance guard, therefore they have to stop to get reorganized again.

BEES BUILDING COMB ON A BUSH WHERE THEY HAD CLUSTERED.

There was a bee-tree cut not very far from our house, and the bees settled on a bush and built some comb, and the queen had laid some eggs in it when papa went and got the bees. Papa takes GLEANINGS and I read lots of pieces in it.

Ashland, Mo. **ROBERT MARTIN, JR.**

What queer freaks bees do have! I suppose the swarm you speak of got demoralized when their nice little home came down with a great crash, and they were ready then to take up with almost any home, even though it be a paltry bush. We have heard of circumstances like this before, but they are not very common. A while ago, you remember, a juvenile told us of a swarm that clustered under an old bench. It stayed there all winter, and didn't die either. We like to have the little folks report any thing of this kind that is a little unusual in regard to bees. Perhaps we shall find that many things are not so uncommon after all.

ERNEST.

RAISING CARP, AND RESULTS.

My pa has a carp-pond. He made it last spring. He sent to Mr. Kaler for a pair of two-year-old carp. He paid $5.00 for them, and $3.50 express, and sent for 100 little ones about 4 inches long, besides. He paid $5.00 for them and $3.65 express. Fifty-seven of them were alive. He drained his pond this fall. The two big ones weighed about 3 lbs. each. The 57 were about 12 inches long. There were 1100 little ones about 4 inches long, and he sold six of them that were 12 inches long for $15.00; sold 43 of the little ones for $7.00, and the rest he put back in the pond. The carp-book said the carp bury themselves in the mud in the winter. That is a mistake. My pa went to the carp-pond to-day and cut a hole in the ice in the middle of the pond, and he took the piece of ice out. It was 7 inches thick, and he saw the carp swim around by the dozens. It was 10 degrees below zero this morning.

EMMA JENSEN, age 11.

Valparaiso, Neb., Dec. 16, 1885.

Why, Emma, your facts are very important, I should say. I guess Mr. Peirce, who wrote the carp-book, will have to tell how it comes that the carp were swimming around when it was 10 degrees below zero. May be the cutting of the ice disturbed them, and will result in their death. I have heard of goldfish being killed by cutting the ice on the pond.

TEARING DOWN CELLS; HOW SOON DO YOUNG QUEENS COMMENCE IT?

Let me ask you a few questions about bees. Do you think that bees will do good where I live? I live where I can see the beach every day. How long is it after the first queen hatches, that she tears down the other cells? **SARAH SOPER.**

Ferndale, Humbolt Co., Cal.

By referring to the map I see you are situated in the northern part of California. The great honey region, however, is more in the southern part of the State; but I should think your locality would be fully as good as Ohio and other States where good yields are obtained.—A young hatched queen will begin to tear down cells very soon if not immediately after she emerges from her own cell. This would depend some on how vigorous she was at the time of hatching. If weakly, she would probably sip at the honey a while and then proceed to annihilate her rival sisters. As far as my observation goes, queens do not tear down the cells themselves, but simply make a small hole through the side of the cell, and leave the bees to complete the job, as they are quick to see whether a cell has thus been punctured. ERNEST.

HOW THE YOUNG FOLKS MANAGE THEIR FATHER'S BEES.

I have a sister and brother who are bee-keepers. Willie stays at home, and Annie attends the yard at Rudleton. There are 97 swarms at Rudleton, and about 78 at home. Annie has kept the yard at Rudleton for three years, and Willie the one at home for four.

I am very much afraid of the bees. Last summer Annie had to stop work, for the bees sometimes were that cross.

HOW TO HIVE A SWARM OF BEES.

A good way to hive bees is: Take a salt-sack and sew the mouth of it to an old barrel-hoop, and have a long pole to it. If the bees are up high you can easily get them down. We spread a white cotton sheet on a table, and set the hive on it, and upset the bag on it, and the bees will crawl right into the hive. You must move the hive on to the stand you want them to occupy, or else you will have them go right to the place where they alighted on the tree after they swarmed. MARTHA MOFFATT.

Maxwell, Ont., Jan. 15, 1886.

Let me see; your father wrote an article for the last GLEANINGS. Has he discovered the art of "making himself useless," and so pressed the younger ones into service? I judge so, if Willie and Annie manage 175 swarms.—The swarming device you mention is illustrated and described in the A B C book, page 253. ERNEST.

CLEANING WAX FROM UTENSILS.

Some time ago I saw a letter from some one, and in it telling how to clean waxed dishes; and I thought by your answer you did not know of any better way, so I concluded to write and tell you how we clean ours. Heat the dish on the stove; and while hot, rub well with any kind of soft grease; then wash with hot soft water and soap, and it will come clean easily, and without any trouble.

AN INTELLIGENT DOG.

I have a sister, Nellie, fourteen years old, and a brother, Lloyd, seven years old. Lloyd has a dog that he thinks a good deal of. When you put your hand on a chair, and "shake hands," he will jump up on the chair and hold out his paw to shake hands. His name is Dash, and he is seven or eight months old. There is a big patch of ice a little way from our house, and sometimes we take the sled over there and Dash will draw us on it, back and forth on the ice; and when we are riding down hill he will, of his own accord, take the end of the rope in his mouth and draw the sled to the top of the hill.

HOW AN ABSCONDING SWARM WAS ARRESTED.

Last summer Lloyd and I saved a swarm of bees for papa. He came from the field where he had been at work, and saw a swarm of bees going off. He grabbed a pail of water and went after them. We watched him until he went down in a valley out of sight, and then Lloyd and I took a pail with some water in it and went after him in hopes of catching up with him and stopping the bees. We ran up hill and down till we had gone about half a mile, and then we saw papa coming to meet us, after the water; but there was not much left, for we had run so fast, and over such rough ground, that we had slopped it all over, but it saved the bees. Papa went to the house and got an old nail-keg, and put them in it and brought them home and hived them.

FRANCES E. WORTH, age 12.

Reading Centre, Schuyler Co., N. Y.

The plan you mention, of cleaning wax, if I mistake not, is a combination of the method given by C. C. Miller, page 704 (to which you refer), and the one given in the A B C book, page 287. Benzine is also there recommended as being effective in removing wax where the utensils are inconvenient to cleanse otherwise. No doubt any one of the plans enumerated answer as well.—Well, I am sure you deserved that swarm of bees, after such a "slopping" over. Did the bees cluster immediately, or soon after the water was thrown upon them? ERNEST.

CHARLIE'S HIVING-BOX.

My papa has taken GLEANINGS ever since I can remember. He has got 75 colonies of bees now. In the summer I help him hive the swarms. Papa has hiving-boxes. They are something like a little hive with an alighting-board and an entrance. They are fastened to the end of a pole. When the bees commence to alight we set the hiving-box up under the bunch of bees. They go into the box. Then we take them down and hive them when we get time. One thing I learned last summer. If you take bees from the entrance of one hive and throw them down on the entrance of another hive, you are pretty sure to get stung. I tried it, and got three stings. CHARLIE H. MASON, age 9.

Mechanic Falls, Maine, Jan. 5, 1886.

Thank you, friend Charlie, for your very plain description of the hiving-box. This, constructed with an alighting-board, would doubtless work very nicely; but I should be afraid that a large swarm of seven or eight frames would be in danger of smothering in a small hive. For that reason the hiving-box figured in the A B C book is perforated by a good many holes. Come to think of it, in our practice in our own apiary we hive swarms very much as you do, only we use a full-sized Simplicity hive. As there are no large trees in our apiary, when a swarm issues it generally clusters on one of the low evergreens on the outskirts of the apiary. We then take a Simplicity hive with some empty combs and a frame of unsealed larvæ and place it so the entrance is directly under the cluster. The hive is held at the right height by one or more Simplicity bodies placed beneath. The bees are soon inside, and the hive is located upon its proper stand. This is the way we generally hive our swarms. So much for no tall trees in the apiary.

ERNEST.

BEES THAT WOULD NOT UNITE; HOW THE ENGRAVINGS FOR GLEANINGS ARE MADE.

I am living at grandpa's, and going to school. Grandpa had 20 live stocks of bees on Jan. 1, for they had a big fly; but he thinks it will be the last one for many of them, the way the winter keeps. Part of the bees are packed in leaves, and fed sugar syrup, and part are in box hives, left on their summer stands, to take their chances of living or dying.

Two seasons in succession have been too poor for honey here. Grandpa tried to double up some by setting one hive on top of another, but they would not go down nor up; so after two weeks he set them off where they belonged, then they were glad, and came out as usual.

I like to read the young folks' letters in GLEANINGS, so I thought I would tell you about our bees, and may be it would not be thrown into the waste-basket. Grandpa wants me to ask you to explain, if you will, just how engraving-plates are made, so you can make a picture of any thing you want; but if there is any secret about the art, let it go. Grandpa doesn't use tobacco any more since he got the smoker you sent him.

MAUDIE MAY MINX, age 10.

Pine Grove, Gallia Co., Ohio.

You ask how our engravings are made. We first take a piece of boxwood or maple, the depth of the type (nearly an inch), and the size of the picture desired. Upon this the engraver draws with a pencil the object he wishes to represent, and then retouches with India ink. The face of the boxwood is very hard and smooth; and when the picture is done, it looks like any pencil-drawing. Next the engraver uses several sharp keen-edged tools with which he carves the block, leaving only the black lines of the pencil. The shading is represented by parallel lines —the darker the shading, the heavier and more compact the lines. When this is done we have a raised picture which prints the lines and delicate shadings just like the types you see in a printing-office. If you notice closely any of the engravings that appear in GLEANINGS you will see what I have explained. Nice engraving is one of the fine arts, and good engravers get high wages—five, ten, or even more dollars per day.—In regard to doubling up, you do not say anywhere that one of the queens was taken away before uniting. From this. and your description of the colonies, we infer that both had a queen after they were doubled up. This might account for their not uniting; though, as is sometimes the case, two colonies are united regardless of queens, when one will be killed by the bees. I should judge that both your grandfather's colonies remained entirely by themselves, not interfering with each other's queen. ERNEST.

Dear Maudie, do you want to know what part of your letter rejoiced my heart more than any thing else? It is, that your grandpa does not use any more tobacco, and that it is his little grandchild who is telling it to the readers of GLEANINGS, and rejoices in her little heart that he is purer in mind, purer in body, and, I am sure, purer in heart, for the sacrifice he has made for his little grandchild's sake, for our sakes, and for the dear Savior's sake. May God bless him, and help him; and may he be cheered by reading in that good old Bible, "Blessed are the pure in heart, for they shall see God."

A DONKEY GETS INTO TROUBLE WITH THE BEES, WHEREUPON HE "BRADE;" PEKIN DUCKS, AND THEIR VALUE IN AN APIARY.

As there is something so original in Joseph's letter we insert it just about as he wrote it, spelling and all.

My "intelligence" is so little, i do not no of any thing to write that will interest, but you must excuse this one, as it is the first. I like to help pa work with the bees except such a one as that cross hybrid stock that stung Pa so much threw his Briches and run him off to the spring and me under the flore. They drove the young mule colt that was 30 feet away, and made him kick and snort; his hare was long, and they tangled in it, but he soon flew a way and "brade" as he run. Pa says the holy land Bees Will suck 3 flours while the italians will suck 2; he says they do not fool time away in Buzing a Round as the italians do. We keep sawdust 3 or 4 in. deep in our apiary; the ants and frogs will not work in it, the frogs have no place to hide as the dust keeps the weeds down; a frog will eat 50 bees, if he can get them. so much for sawdust. The Pecan Ducks has a good chance to ketch the moth miller between sundown and dark. The ducks go among the hives every evening and ketch every miller that flies; no grass in thear way, so they always lit on Pekins, every one that fly. These ducks is worth keeping for this alone; be sids each duck will lay 200 large egs every year, then they weigh 15 lbs. to pare of 2. The feathers is beautiful and white, and the meat is as nice as chicken. So come and see us and wee will have a big fat one for dinner. JOSEPH S. G.

So it is a donkey this time, and not a horse that meets with a mishap among the bees. No wonder the poor fellow "brade" when a lot of hybrids got after him. I think we shall have to conclude that it is *never* safe to have our domestic animals anywhere near the bees.—I have sometimes thought that the Holy Lands seemed more industrious than the Italians; but for some reason they never seem to have very much honey in the hive. Perhaps it is their disposition to breed so heavily that keeps their supply of honey low.—An apiary with sawdust three or four inches deep makes a very pretty appearance; but in time, according to our experience, the weeds will come. As to toads, I suppose the sawdust answers very well. You say a toad will eat 50 bees. Did you ever count the number? Last month a little girl told us of a toad eating, by actual count, 150 flies, so I presume it would be no very great task for Mr. Toad to eat 50 bees. That being the case, they are not very profitable in the apiary.—We are glad to know that Pekin ducks are valuable in the apiary, for getting rid of moths. We have a pair of them in our poultry-yard, and I don't doubt but that they would render very good service, providing it were something to eat, for they are big eaters.—You have given us so many good points that I think you are entitled to a chromo. ERNEST.

Friend Joseph, I want to add a word to what Ernest has said in regard to your little letter. It is full of original thoughts, and shows a progressive spirit for one so young —at least, we suppose you are quite a small boy, although you do not give us your age; and in regard to the spelling, you have probably done tiptop for so small a boy. We give your letter just as it was written, so the juveniles can exercise their talents in the line of proof-reading by correcting all the mistakes made. Now, then, who will count up and see how many errors there are in Joseph's letter of 27 lines?

OUR HOMES.

Supper being ended, the devil . . . . put it into the heart of Judas Iscariot, Simon's son, to betray him.—JOHN 13: 2.

WHO is there who has not pondered over this strange and apparently incomprehensible matter of sin in the human heart? We might almost think that poor Judas was not very much to blame here. Sometimes we are almost inclined to think it was the devil's fault entirely. Had he left poor Judas alone, Judas might have been as good as any of the rest of the disciples. These questions are undoubtedly beyond our province; but even if they are, does it follow that the other disciples were left alone? Didn't Satan try them, each and all? What is sin, any way, and what is the use of it? I speak reverently, without any disposition to question the wisdom of the Almighty. In fact, I wish in this paper to help you all, dear friends, toward a better comprehension of God's wisdom, goodness, and love to us, his poor fallen creatures.

A temperance lecturer gave me a vivid idea of sin, a few evenings since, when, perhaps, he did not intend to. He was likening intemperance to the cholera, and he spoke of the time when the cholera threatened to invade the shores of America. He told how we all went to work, not only in the large cities, but in the towns and villages, to prepare to meet the dreaded foe. We established boards of health, who went around and examined the cellars and outbuildings, and they were clothed with authority to demand and insist that the people should be clean, and take care of themselves. Our cities were purified and slicked up; our most intelligent physicians and scientists pointed out the probable cause of such epidemics, and from one end of the land to the other a general reform was inaugurated. Did we meet and conquer the foe? Yea, more. The result was as any sane man or woman might have guessed. Not only did we keep away the cholera, but the death-rate was rendered less, to the number of inhabitants, than it had ever been before. We demonstrated, by figures, that not only cholera, but typhoid fever, yellow fever, and no one knows how many other ailments, were capable of being controlled. We began to see that disease could be led captive, the same way in which father Cole has "the waters led captive." The point the lecturer made was this: Who did this, and who should have the credit of it? Was it the Republicans? Surely not. No such thought was ever uttered, that to the Republicans belonged the credit of the sanitary measures put in force in our cities. Well, was it the Democrats? Why, no. Was it the Prohibitionists, or were the Prohibitionists more active than any of the other parties in this matter? True, they might have been, and may be they were; in fact, I think they *ought to have been*, according to their profession; but nobody ever mentioned it, if such was the case. Neither was it any religious sect, nor was it the women who led the movement principally. Of course, they did their part, and may be in one sense they took the lead, because women are naturally more in favor of order, cleanliness, and purity, than the men are; but they never claimed any more credit, and no one ever claimed it for them. To whom, then, does the credit belong? Why, to all of us. The people united, no matter what were their politics, religion, age, or sex; and when you get our American people united on any thing, we are *bound* to succeed. Did you know it, my friend? Well, why can't we be united in other good works? Why not be united in resisting Satan, the prince of all evil, and the prince of the powers of darkness. Why, the great truth lies here: The cholera was a common foe; the cholera hadn't a friend any where. Even the man or woman who had determined on suicide didn't want the cholera. He was recognized as a universal enemy and fiend, and we massed our powers against him. Now, then, why not do the same way with intemperance? or, if you choose, why not do the same with sin and Satan in *every* form? Because men *love* evil in its varied forms. Jesus told us, centuries ago, that "men loved darkness rather than light, *because* their deeds were evil." But, why do men love evil? To get a better view of it, why do *we* love evil? Why shouldn't evil be like the cholera—a hideous and hated foe to every one? Perhaps, had Adam not fallen, such might have been the case; but so long as the fact remains that it is *not* the case, and that we, for the time being, love sin and Satan, will it not be wisest for us to meet it as it is? We are in a fallen world: what shall we do?

I have talked to you at different times, of late, in regard to making the elements, that do us harm, our servants. The sudden and terrible frosts of winter get into our cellars, and freeze our vegetables, and away go hundreds of dollars in a single night, because we didn't expect such a freeze. During this present winter, we are told that the friends in Florida have suffered the loss of over a million of dollars by the freezing of their oranges, and that such a frost has not been known before for over fifty years. Shall we sit down helpless before old Boreas, and call it a "dispensation from God," and say there is no help? God forbid! By the help of science, we shall get more and more able to manage these erratic forces of nature. Let us employ these freezes in converting water into big blocks of ice; and let us carry the big blocks of ice into these same cellars, and make them arrest rot and decay in these same fruits and vegetables that the frost was before liable to destroy. By recent inventions in cold-storage rooms, apples can be kept safely from one year to another. Strawberries can be bought up, when five cents a quart, and kept until the glut in the market has passed by, and then sold at good paying prices. We do this by simply knowing how. The frost becomes our *humble* and *obedient servant*, and does our bidding so faithfully that a good cold-storage room need not vary more than two or three degrees in a year. Careful experiments have shown us just what temperature apples and strawberries, and other commodities, should be kept in to preserve them from either becoming spoiled by too much heat, or from freezing; and with a properly arranged cold-storage room, the matter is a complete success. Now for the application.

A good many of us have hasty tempers. I do not know that *hasty* is the right word. Some of us have tempers that are slow, and yet unmanageable even then. Perhaps they are the curse of our lives: what shall we do with them? I will tell you, friends. By the help of God we can handle them as we do the frosts of winter. When the temper comes up, and you recognize it boiling and seething to get out, set it to work making great blocks of ice, as it were. Put these blocks away until you need them. They will prove to be a tremendous motive power, if properly managed. Don't kill out a boy's spunk; find some place where he can use it and utilize it, and he will be as great a power for good as he has been for evil. The temper needs to be a *sanctified* temper, and I believe that such a thing is possible. Let me tell you a little of myself.

Sometimes, on going my rounds after the work is over for the day, I find property scattered about in heedless disorder. The vegetables and fruits that should be in the cold cellar are left, may be, near the steam-pipes, while something that should be kept warm is possibly put where it will freeze. May be I have talked with the one who left them so repeatedly, and it does not do any good. His mind is on something else. Perhaps he cares more for the small wages he receives, than for the welfare of property worth ten times these wages. My temper comes up. I try to put the subject out of my mind, but it won't come away. Perhaps it is Saturday night, and I begin thinking, "There, my enjoyment of the Sabbath is all gone, for I feel so worked up by this matter." May be, instead of the loss of property, some new convert in whom I had much faith has been going off with a crowd of boys, to go in swimming on Sunday; or perhaps some one who has given me the most faithful promise in regard to tobacco has been smoking on the streets. Satan tries to enter my heart, or tries to tempt me, and suggests, "I wouldn't fuss or bother any more with that miserable specimen of humanity. I would send him somewhere else for a job, so quick he wouldn't know what is the matter with him, and I wouldn't wear out my life and strength in chasing around after any more people, so utterly unprincipled and irresponsible." Dear friend, do you suppose I feel happy when I arrive at such conclusions? Why, bless your heart, no. If I allow my mind to dwell on it, the more the feeling of indignation wells up, and I begin recounting all the kind acts I have done, and thinking, "And that is just the pay I get for it—that is my reward." Then I remember some one else who has made a bad mess of something or other, and I feel like saying, "I am going to give the whole thing up, and not try any more." I remember the boys in jail. It is too bad to chop right off, and not visit them any more. But Satan suggests, "You might just as well. This has so upset you, that you haven't any spirituality left any way;" and for the time being I actually think and believe that all the enjoyment of the coming Sabbath is surely at an end. However, I conclude to go through with the duties that lie before me, the best I know how, keeping it all to myself, and bearing it as best I can. About this time it occurs to me that I have proven, by hundreds and hundreds of similar experiences, that the only outlet is to go down on my knees and tell my troubles to the Friend of sinners. Is it right to get down on your knees when you are mad? Why, to be sure it is—that is, providing your "mad" is not the kind that prompts you to turn from the Savior. If you are vexed and disturbed, but still *loyal* to him, *by all means* go down on your knees. Just let loose your feelings, or, in other words, take one of those big blocks of subdued temper and tumble it at the Savior's feet. Tell him your troubles and trials; ask him to help you to honor him in whatever you do; and if, when you get up, you haven't got clear out of the toils of the tempter, don't worry nor trouble yourself very much. Pitch into business; straighten up the things that are wrong, *yourself*. Make up your mind to bear the burdens of the world, even as the Savior bore them; decide to be patient andlong-suffering for his sake, if not for their sakes. in other words, take your cross and follow the Master.

> Then said Jesus unto his disciples, if any man will come after me, let him deny himself, and take up his cross and follow me.

Whenever the subject comes up again to annoy you, put it persistently out of your mind. If it should occur to you during the sermon on the Sabbath, just say over to yourself, "Remember the Sabbath day to keep it holy," and stop thinking about it, and, first you know, the matter will dwindle into insignificance, and you will be surprised to find yourself happy and peaceful. I remember how, years ago, when I had started to go to my mission Sabbath-school, full of the spirit of the Master, and thoroughly happy, on my way I passed through a field of my buckwheat, just beginning to ripen into seeds. I picked off a few, and was startled to notice that it looked like common buckwheat instead of silverhull, which we meant to have sown. All at once my mind suddenly reverted to the time when one of the hands moved some bags of buckwheat, and in a minute it was clear to me (or at least I thought it was) that that heedless hand had been the cause of making that a beautiful field of common old-fashioned buckwheat, instead of silverhull. My face grew hot with impatience. I fought and struggled against the tempter; but the vexation was so great, that every spark of God's Spirit seemed to be quenched out of me, like the blowing-out of a lamp. I dare not put on paper the bitter feelings I had toward that careless hand. Why, my friends, if your temper is like mine under such provocations, may God in his mercy have pity on you. My mother used to tell me, when I was a child (as I have mentioned before, perhaps), that I would surely die on the gallows, if I gave way to such spells. Some of you may say, "Why, Mr. Root, I thought you professed to be a Christian. Here you are making a confession of getting mad, even so your face was flushed, and that, too, on the Sabbath day, when you are on your way to a mission Sabbath-school to teach a lot of children, and a little community, the way of eternal life. Shame on you, for a hypocrite!" Hold on, hold on, my friend. I was terribly vexed and stirred up, and my heart seemed to beat like a small locomotive; and right here I want to thank God for having put a small locomotive in even this feeble frame. It was bad, I know. My temper should have been more perfectly sanctified; but, dear friends, the but recently converted boy was doing the best he could. I was alone in the fields. I was under God's blue sky, and under his overshadowing love as well, I am sure. I prayed him to take the tempter away. I have sometimes wondered why he didn't do it. I prayed for perhaps nearly half the way of that five-mile walk to my school; but it was some time before the fierce passion began to "let up." How about the school? Why, God took care of the school, and he took care of me, and it went off all right, and I came home breathing praises, and singing, "Thy will be done," or something to that effect.

On Monday morning I examined into the seeds carefully, and found there was no mistake in the sowing. I also discovered that silverhull buckwheat looks very dark, or almost black, when it first ripens in the field, but that the silvery look comes on afterward.

Do you want to know what good came of this little experience? Why, it resulted in making a good lot of great blocks of—what shall I call it?—subdued and sanctified energy—a kind of energy and push, freezing up, as it were, like the blocks of ice, to be kept until it could do some work. The work done was a vehement determination to have our seeds so perfectly labeled, inside the bags and outside the bags, that no such accident could happen as happened that year; that is, such an accident as happened only in my imagination and uncharitableness. This very event, perhaps, did more toward building up an immense trade in seeds, than almost any thing else could have done. A sanctified temper that was piled up that day, is, some of it, there yet; and when I find a lot of seeds not plainly labeled in at least *two* different places, the energy stored up begins to make itself shown. Is it not well, for me at least, that God has permitted me to be tried, and severely tried? Do you remember the lines of the little hymn I have several times told you about?—

Joy to find, in every station,
Something still to do or *bear*.

In my case, my temper came up that day a good deal because my whole heart and soul were so taken up with raising honey-plants, and testing them, that I should have been terribly disappointed if the right kind of seed had not been sown. My feeling was in some respects commendable, but I was wrong in being impatient or hasty. A great many other times in my life, when I have been sorely tried by disappointments because of some such accident, instead of venting my spite by harsh and unkind words, I have gone off by myself and poured out my soul in prayer, asking God to use this intense determination to have a better state of affairs; and when I started back to my work I have felt like saying to myself something like this: "Now, *you see* if I don't have this thing fixed in some way so that this blunder *can't* happen again," and the energy and determination was the very thing which pushed me toward some important invention—not only helping myself, but you also, through the medium of these pages of GLEANINGS.

But, how shall we make an appetite for strong drink or tobacco, or something of that kind, work out good? How shall we freeze *this* sin into blocks of ice, to be saved up? Perhaps we can manage as father Cole has managed with the rains and floods—drop them down out of the way, where they will be harmless, but where they may at some time do us good service, after the harm is past. Satan sometimes gets hold of us because we are uneasy and discontented. We want something, or want to go somewhere. Because we feel uneasy we let our minds wander toward the forbidden thing. We want some excitement, or something to do. Life as it is, is too monotonous. I have been through all these experiences, and I will tell you what I did. I prayed God to help me to put his image in the place of the thing that would do me harm. I prayed him to help me to substitute, in place of the thing that would harm me, and harm my fellow-men, a love for my Savior that would surely do *good* to my fellow-men, and the prayer has been over and over again answered. I have lately been thanking God for giving me such a keen zest and enjoyment in raising plants and vegetables, and I have thanked him for the consciousness that this is an innocent and harmless amusement, if nothing more, and I have certainly never enjoyed any thing else so much in my life—no, not in the whole forty-six years of my life, even including happy childhood. We want to let these lower appetites and passions down on a lower level, where they belong, where they will be servants and not masters, just as friend Cole lets down the water from the rains. God's Spirit is to rule, and these other things are to be secondary.

A great temperance movement has taken place in our town, and this morning almost all the hard drinkers here are wearing the blue ribbon. Last evening we were disappointed in getting a speaker from abroad, and so the responsibility fell on our home talent. A hard-working man, whom I have known for fifteen or twenty years, and one whom I have seen go down into intemperance, and come up through a Murphy pledge more than ten years ago, after much urging took the floor. He told us about the conflict of ten years with this fierce appetite. Three points come right in with this Home Paper, and I want to mention them. Satan tried to enter his heart again, as he did with Judas, and this is the way our friend resisted. He said there were times, especially toward the close of the day, when it seemed as if he could not live without a drink; but he went resolutely home, kept away from evil associates and temptations, and went to bed without the drink. In the morning it was all over. The fierce gnawings of appetite were gone, and gone a thousand times better than had he given way to it. He said this not only happened for months, but for years. Finally he was taken sick, and came near death. The doctors gave whisky, as usual. When he began to come to himself a little, he tasted the whisky in his medicine, and remonstrated with his attendant, a near neighbor. The neighbor told him he must take it, or else death would probably result. Well, our friend John is an Englishman, and he has his full share of English spunk and stubbornness; in other words, he has a good "big chunk" of a temper, like myself. He replied, that he was not going to take whisky for *anybody*. They sent for the doctor.

I can not give his exact words, but the substance of them is about like this.

"Mr. E., this is serious business."

"Well, doctor, that is exactly what I think."

"If you take the stimulant we think best for you, you will probably get well; unless you do take it, we don't see any help for you."

Still our English friend was immovable, and the doctor resumed:

"Mr. E., which would you rather do—take whisky, and get well, or go without it, and die?"

The old hero looked the doctor full in the face, and quietly replied, "*I would rather die.*"

At this point in his speech the audience encored until it seemed as if the building would come to pieces. Now, boys, *that* is *the doctrine.* When Satan tries to enter your heart, tell him squarely and decidedly, "*I would rather die.*" Was this foolhardy? Not a bit of it. Which is better—to live, with a great prospect of dying eventually the death of a drunkard, or dying an honest death, free from the influence of stimulants? "What shall it profit a man, etc.?" What are a few years of life worth, providing the life is a life of sin? When Mr. E. first signed the pledge, it was at a Murphy meeting. He had always been much in the habit of staying at home on Sundays; but this Sunday evening, as he was out later than usual, his wife looked up inquiringly.

"Where have you been, John?"

"I have been at the temperance meeting."

She looked up, somewhat astonished.

"What did you do there?"

He put his hand in his pocket, and took out a Murphy card, and showed it to her. Poor woman! She, like the rest of us, lacked faith, and inquired if he thought he could keep it.

"Jane," said he, "did you ever know me to sign my name to a paper when my signature didn't mean something?"

"No, John, I never saw your name signed to a paper unless it meant all that was written above it."

She took the little card and framed it with a fancy frame of straw, worked out by her own hands, for she is an English woman, and understands fancy straw-work, and hung it up on the wall, and whenever John looked up at the clock to see the time of day, there stood his Murphy pledge, right above his own handwriting. It was an *object-lesson*, and a reminder. And so John pulled through the years as they passed by. He has now a nice little home; bright and educated children, and he is a man whom the town of Medina delights to honor.

Dear reader, do you see that even an Englishman's stubbornness can be made to serve God? And do you see now that what is needed to bring about this glad millennium in our United States of America is, that these tempers and this stubbornness shall be sanctified and consecrated, and laid at the feet of Christ, telling him, "Here, Lord, I bring myself and all that I have—my appetites, my passions, my fierce temper, and lay them all at thy feet; and I ask thee to help me to say in real earnest, 'Get thee behind me, Satan.' And when the devil shall try to put it into my heart to do evil, and forget thee, may I, too, have grace and strength to say, 'I would rather die.'"

I need not add, that our friend did not die, in spite of what the doctor said; neither will *you* die either, my friend, although you may think you are going to die; for has not the Savior said,

> Whosoever liveth and believeth in me shall never die?

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, FEB. 15, 1886.

> Thou art weighed in the balances, and art found wanting.
> —DAN. 5:27.

PRICE OF 241-LB. SCALE REDUCED.

WE are pleased to tell you that we are able to sell these at $3.50 each, or $6.50 for two, and the double beam one-third more. These are the same scales that we have sold for years; and as the manufacturers gave us a better rate this year, we take pleasure in giving our customers the benefit of the reduction.

A CORRECTION.

IN noticing circulars received, in our issue for Jan. 1, we gave the address of J. D. Rusk, Milwaukee, *Oregon*, as Milwaukee, *Wisconsin*, which last is wrong. While we are about it, we must say we think it somewhat unfortunate to name new and small towns New York, Chicago, Philadelphia, etc., when plenty of other good names can be found; and this hint is in accordance with the suggestions of the U. S. Postoffice Department.

PERHAPS I should tell the juveniles, that in the picture on page 142, of our greenhouse, the figures in the foreground are supposed to be myself and Huber. The picture of myself is pretty fair, only the engraver doubtless supposed that the sun was shining from the west, and so he pushed my cap down over my eyes, as you see. He has got Huber pretty fairly, only he ought to have pictured him about half as tall as his papa.

ANOTHER USE FOR THE TRANSPLANTING-FRAME.

THE transplanting-frame, shown on page 136, is also an excellent arrangement for sowing seeds of certain kinds. We have some beautiful beds of onions, made by putting the onion-sets, one in the center of a row of meshes, then skipping a row, etc. Beets, also, may be quickly and accurately sown in the same way. By means of this frame, any child can put in seeds, and get the spacing exactly right. All you have to do is to pick up the frame, and put it down again until the seeds are in.

160,000 SECTIONS AT $2.25 PER 1000.

WE guarantee our first-quality sections to be equal to or better than any in the market; and in order to make them so, we have culled out all that are colored, or in any way not up to the standard. Now, these second-quality sections are like "thirds" in crockery—they are just as good for service, but do not look quite as well as firsts. We have now in stock 160,000 of these sections; and as long as we have any on hand we will sell them at half price of the first quality; i. e., $2.25 per 1000; or, for 5000 or over, $2.00 per 1000.

SEEDS OF BASSWOOD-TREES.

SINCE writing on page 143, in regard to this matter, we have received the following from friend Kendel, of the Cleveland seedstore:

> The seed of basswood and linden can undoubtedly be obtained now; but, how about its germinating? We can not tell. The last, and, in fact, all the tests we have made in hot-beds have utterly failed. A. C. KENDEL.
> Cleveland, O., Feb. 9, 1886.

In view of the above, probably we shall have to give up the seeds; but I discover that E. H. Ricker & Co., of Elgin, Ill., advertise European linden seedlings at $8.00 per 1000. Now, who is there who can furnish us seedlings of the American linden, at as low a price, or still lower? And who can tell us about the quantity of honey European linden furnishes, compared with our American? I know this ground has been gone over before, but I don't think it will hurt us to consider it again.

REDUCTION IN PRICE OF WIDE FRAMES.

By the new method of filing saws, we do away with the planer on sections, frames, etc., and turn out nicer work, smoother and better finished, than ever before. Besides making them nicer, we can also sell them cheaper. Wide frames in the flat, Simp. size, to hold 8 sections, or the same crosswise Simp. to hold six sections, or, either one one-half depth to hold 4 and 3 sections, also 3 section-cases—any of these we can furnish at $2.00 per 100 or $18.00 per 1000. For odd sizes we always charge $1.00 for setting machines, then you may have any quantity at regular prices.

ANOTHER IDEA IN REGARD TO REVERSIBLE HIVES.

SINCE brood combs of half depth are brought up again, some friend, whose name I have forgotten, suggests that there is not much need of reversing frames when we can reverse the position of these shallow frames so easily. For instance, we have made L. brood-frames of half depth, with half-depth Simplicity bodies to match, for years. In fact, there have been so many calls for them that we have them in stock in case of possible orders. Well, when the bees get the brood pretty well in the lower set, and capped honey, a good deal of it, in the upper set, instead of reversing any of the frames, simply put the upper set on the bottom-board, and the lower set over them. This brings the sealed honey right in the center of the brood-nest, and the bees would probably take it up and put it in the sections, as well as if the frames were reversed, or nearly as well. Have any of the friends been in the habit of working half-depth frames in this way? Half-depth wide frames have also been made for these half-depth Simplicities; in fact, they are in our price list, and have been for years.

BEANS, FOR MAKING HENS LAY.

IN our issue for January 15 I mentioned that we got only one egg a day from about a dozen hens. Well, some time ago we bought quite a lot of white-marrow beans from a farmer—so many that we hand-picked out about a bushel of beans, off in color, etc. The women were going to throw these beans away, but I suggested that they be cooked, and given to the chickens. We tried them first with about a pailful. Well, our flock of hens, with a little assistance from the rabbits and ducks, ate most of the pailful at a meal. What do you think the result was? One egg the next morning before breakfast time (*my* breakfast time, not the hens'), and two more during the day; and although the weather has been down close to zero, we get four or five eggs a day ever since the diet of cooked beans was adopted. Some of the same food was given to the flock at the warehouse, and they commenced laying too, although the weather was so cold their eggs froze before we found them. Now, was this simply the result of a change of diet, or are unsalable beans cheaper and better than the much-lauded egg-foods? Before the beans were fed, the fowls had wheat, oats, and bone meal, as well as soft cabbage-heads, all they would eat. I leave the question with the editors of our poultry-journals to answer. The following is clipped from the *Practical Farmer:*

> There are countries where the almost exclusive diet of the masses is beans. These contain 87 per cent of nutriment.

Now, beans fit for poultry can probably be bought for a dollar a bushel or less. Refuse beans, thrown out by hand-picking, should be procurable at a very low price. For some time I purchased wheat-screenings at a cost of 40 cts. a bushel; but when I discovered that I could get good sound wheat for from 85 to 90 cts., I decided that the wheat was cheaper, and I think so yet. Now, is not a bushel of beans worth as much, or more, than a bushel of wheat, besides the tendency they seem to have to produce egg-laying?

ALLEY'S
DRONE & QUEEN TRAP.
Send 65c. and get sample by return mail.
HENRY ALLEY, Wenham, Mass.

For Sale. I have a Root $25.00 fdn. mill, bought about three years since, almost as good as new, with dipping-tank and all complete. They cost me, when new, $27.50, and $7.00 duty. I wish to sell them, and will take $18.00 for them. A. W. WILLOWS.
4tfdb Carlingford, Ontario, Canada.

Bee-Keepers' Supplies.

Specialists in Italian-Queen Rearing

Order early, to give us the pleasure of filling orders promptly, by return mail — a pleasure to the sender and to the buyer. All from imported stock. We have no others. Prices: Untested, $1.00; tested, $2.00; dozen, $10.00. To dealers, special rates.

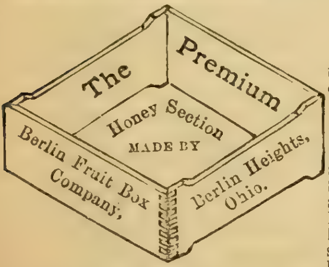
3-4d **Loreauville, Iberia Parish, La.**

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was $40.00, but we will now sell it at half price, or $20.00.

Also one exactly like it, owned by W. W. Bliss, of Duarte, Los Angeles Co., Cal. There is nothing wrong with these mills, except that the rolls are of smaller diameter than those we now make, in consequence of which they do not make quite so thin fdn. right in the middle of the rolls as those made now with rolls of a larger diameter. They will, however, roll narrow sheets equal to any, and will roll sheets a foot wide; but when of so great a width, the center is a trifle thicker, as explained above.

A. I. ROOT, Medina, O.



Awarded

First Premium twice, and the only instances they ever competed, in 1884 at Michigan State Fair, and in 1885 at the Inter-State Fair, held at St. Joseph, Mo. The excellence of these sections is acknowledged by many leading bee-keepers amongst whom are the following, who handle and use them:

Chas. Dadant & Son, Hamilton, Ill.; F. L. Dougherty, Indianapolis, Ind.; M. H. Hunt, Bell Branch, Mich.; Hemphill & Goodman, Elsberry, Mo.; G. W. Demaree, Christiansburg, Ky.; Theo. Thomas, Pleasant Valley, N. Y.; H. R. Boardman, East Townsend, Ohio.

The last-named gentleman writes us, "The lot of sections I got of you (10,000) were very nice and perfect. I am not satisfied in saying I was pleased with them—I was delighted. They were bright and perfect as new-made coin. I have no hesitancy in saying that your make of sections is superior to any I ever saw. There is practically no breakage in folding. In trying them I folded 1000 without breaking a piece."

Our improved facilities for manufacturing these sections enable us to offer them at greatly reduced rates. Send for price list. Address as above. We also make the best berry-baskets in the market.

2 3-4d

GREAT REDUCTION IN PRICES.

Our beautiful all-in-one-piece sections, smooth inside and out, at $4.00 per 1000. For larger lots, write for prices. Send for price list of other supplies.

BINGHAM SMOKERS

LAST AND PLEASE.

CLEREMONT, VA., Feb. 9, 1886.

Messrs. Bingham & Hetherington:—

Dear Sirs:—Please find inclosed $2 00, for which send, per return mail, a Bingham "Doctor" smoker. Respectfully yours, S. H. HUTCHINSON.

INDEPENDENCE, CAL., Jan. 2, 1886.

Messrs. Bingham & Hetherington:—Dear Sirs:—

The "Doctor" came to hand last night in good order. "It is a Daisy." Won't the little pets wink their eyes when they get some of his medicine? I have one of your "Large" smokers, which has been in use six years.

Respectfully yours, WM. MUTH-RASMUSSEN.

Bingham Smokers and Knives sent per mail, postpaid, at 65 cts. to $2.00. Send for free circular to

5tfd **BINGHAM & HETHERINGTON, ABRONIA, MICH.**

HONEY AND BEESWAX.

Our market, and location as a trade center, the rapid growth of our city and country, gives us a large demand for honey. We have found it impossible to keep a stock of 1-lb. frames, unglassed, and of which we are in need. This style of comb sells much faster than any other and we will make liberal offers on receipt of samples. We are well stocked on 2-lb. sections, also extracted. Beeswax wanted on commission. **CLEMONS, CLOON & CO.,**

KANSAS CITY, MO.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

SOUTHERN HEADQUARTERS

FOR EARLY QUEENS,

Nuclei, and full colonies. The manufacture of hives, sections, frames, feeders, foundation, etc., a specialty. Superior work and best material at "let-live" prices. Steam factory, fully equipped, with the latest and most approved machinery. Send for my illustrated catalogue. Address

5tfd **J. P. H. BROWN, Augusta, Ga.**

LOOK HERE.

New Factory, new Machinery. Having owned and handled bees for twenty-two years, I now offer

APIARIAN SUPPLIES

Of my own manufacture. Our specialty will be on one-piece V-groove buckeye sections. You can not guess how white and beautiful they are. We make hives to order, of all sizes and patterns, though the hive *we* use is the Scientific hive, made in sections six inches high, put together without nails. Also Frames and Sections. We claim that we can get more section-box honey from this hive than any hive we know of. For circular, address

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.
10	1	1 roll of 72 s. f.
20	3	3 rolls of 166 s. f. each
22	1	1 roll of 160 s. f.
24	3	3 rolls of 200 s. f.
26	71	22 rolls of 217, 38 of 216, 2 of 195, 1 of 156, 2 of 215, 1 of 210 s. f.
28	13	10 rolls of 233, and 2 of 234, s. f.
34	7	5 rolls of 281 s. f.
38	37	28 rolls of 316, 2 of 285, 2 of 317, 1 each of 190, 632, 126, and 215 s. f.
42	1	1 roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
46	1	1 roll of 152 s. f.
48	4	4 rolls of 400 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
22	1 roll each of 88, 143, 92 s. f.
24	43 rolls of 200 sq. ft. each; 1 each of 120, 168, 190, 40, 150, 140 140 sq. ft.
26	57 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 54, 204 sq. ft.
28	73 rolls of 233, 11 of 224, 3 of 219, 8 of 222, sq. ft.; 1 each of 70, 245, 257, 93 sq. ft.
30	36 rolls of 250 sq. ft.; 1 each of 137, 225, 125, 125, 220, 227, 237, 235, 275, 240 sq. ft.

HONEY COLUMN.

CITY MARKETS.

CLEVELAND.—*Honey.*—The honey market is very good just now for best 1-lb. white, at 14, with an occasional sale of a single crate at 15. Second grade, 13; 2-lb. sections, best white, 13c. Old, 10@11. Extracted, 7@8. *Beeswax*, 25. A. C. KENDEL,
Feb. 20, 1886. 115 Ontario St., Cleveland, Ohio.

CHICAGO.—*Honey.*—Choice comb honey is in good demand at 16c per pound. The best lots arriving here are from New York State and N. Ohio. Extracted sells from 6@8c, and in fair demand. *Beeswax*, 25@26c. All grades are wanted in this market at present. R. A. BURNETT,
Feb. 25, 1886. 161 S. Water St., Chicago, Ill.

DETROIT.—*Honey.*—No change in the honey market; very slow sales, at prices last quoted; viz., 14c for best white in pound sections, in clean cases. *Beeswax*, 23@25c. M. H. HUNT,
Feb. 22, 1886. Bell Branch, Mich.

BOSTON. — *Honey.* — 1-lb. sections, 13 @ 14; 2-lbs., 11@12; Slow sale. Extracted honey, 6@8. *Beeswax*, 28. BLAKE & RIPLEY,
Feb. 22, 1886. 57 Chatham St., Boston, Mass.

ST. LOUIS. — *Honey.* — We quote comb honey in better demand. Good bright stock, 12½c. Extracted, 8c in large cans; 9c in small cans. Case honey has good demand. *Beeswax* wanted at 23c.
Feb. 23, 1886. W. T. ANDERSON & CO.,
104 N. 3d Street, St. Louis, Mo.

MILWAUKEE. — *Honey.* — The demand for choice comb honey in sections has been much improved of late, and selling at 15@16c readily, and we think, if extra fine quality, could get 17c. We will quote 1-lb. sections, choice, 15@17. Dark honey very slow. 12@13. Extracted, scarce, and wanted, 7@8c; old comb, 12½@13. A. V. BISHOP,
Feb. 20, 1886. 142 W. Water St., Milwaukee, Wis.

NEW YORK.—*Honey.*—There is no remarkable change in the honey market. The demand keeps up as we expected, and before long all first class honey will be cleaned out.
Feb. 23, 1886. THURBER, WHYLAND & CO.,
Reade & Hudson Sts., New York.

KANSAS CITY.—*Honey.*—Sales are improving, and we have a good trade in comb, although prices are not as firm, owing to good prospects in California for a big crop, having reduced their prices about 2 cts. Choice comb, 1-lb. sections, 16; fair and dark, 12@14; 2-lb. sections, 12@14; extracted, dull and slow. Dark, 3½ to 4; white, 6@7. *Beeswax*, 23.
Feb. 22, 1886. CLEMONS, CLOON & CO.,
Cor. Fourth & Walnut St's, Kansas City, Mo.

CINCINNATI. — *Honey.* — There is no speculation whatever in the market, and demand is slow for extracted honey from manufacturers, while it is fair for honey in glass jars for table use. Demand for comb honey is slow, and the market is well supplied with all kinds. Extracted honey brings 4@8c on arrival, and choice comb honey brings 12@15c per lb. in a jobbing way. *Beeswax.* — There is a good home demand for beeswax, while arrivals are slow. We pay 25@27c per lb. for good yellow to choice, on arrival. CHAS. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
Feb. 24, 1886. Cincinnati, Ohio.

FOR SALE—1500 lbs. of white-clover and linn extracted honey, put up in new oak kegs, of 175 lbs. each, delivered on board cars here for 8c per lb.
F. W. HOLMES, Coopersville, Mich.

BEES & PLANTS.

20 stands of Italians at $5.00; and 20 stands of hybrids at $4.00 per stand, all in Simplicity hives of Root's pattern. Also pure Gregg, Cuthbert, and Turner raspberry-plants for sale at $1.00 per 100, or $8.00 per 1000. Address

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00, 10 or more, 75 cts. each. Single Number, 5 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

OUR OWN APIARY.

EXPERIMENTS WITH THE SOLAR WAX-EXTRACTOR IN THE MONTH OF FEBRUARY.

ABOUT the 12th day of February was beautiful balmy weather, during which time the outside temperature ranged about 50°. While strolling among the hives, listening to the happy hum of a few bees in the air, the thought came all once to me, Why not, with an out door temperature of 50°, make a test of the solar wax-extractor J. A. Green has just sent?* In response to the request made in GLEANINGS, he constructed this as he would have it, and forwarded the same to us. A moment later I could be seen tugging at a big brown box, wondering what could be done with it in a February sun. I soon had it in position—both the reflector and the tray itself, so as to give the best effect. I then placed, inside the extractor, a 15-cent thermometer in one corner, and some old scraps of comb. With bated breath I anxiously awaited the results. Inside the extractor, almost immediately, but slowly, the mercury began to rise very perceptibly; soon the thermometer indicated 100°. Scarcely imagining that it would go higher, I went away; and when I returned, shortly after, the temperature indicated was 155°.

"Whew!" thought I; "it can never get higher than that, this weather."

It is laid down in the text-books, that wax melts at about 145°. Sure enough, the wax in the extractor was now melting at a fair rate. Again I left; and when I came back, the tube of the thermometer was "clear up full," so that the mercury could rise no higher. The temperature thus indicated was 173°. It did not take me long to procure the best thermometer we had; but by the time I had put it in place of the cheaper one, the sky began to grow a little hazy, so that I could not determine what the results would have been.

While the temperature was up to 170°, as before stated, I remarked to father, who was otherwise occupied in his prepared garden soil, "The comb doesn't melt any more."

"Oh, yes," said he, on coming up, "it is all melted."

I took out a piece of comb (whew! it's hot!), and, sure enough, below the perforated metal were as beautiful yellow wax pellets as one ever saw; and all that remained of the comb now was the cocoons. In appearance, the comb was as perfect as before, though the wax was all, or nearly all, melted off. Of combs that were not more than a year old, scarcely any thing remained. For this reason, one is liable to be deceived and think that his solar wax-extractor is not working. If the combs were mashed up into balls, different results would doubtless be obtained, though I did not try it.

Surely, if the sun extractor will give tolerably fair results in this climate, no one will argue that they are not adapted to the colder climates in summer.

FRIEND GREEN'S EXTRACTOR WITH OUR MODIFICATIONS.

Our foreman of the lumber department constructed another like the one sent us, with a few slight changes. The modification consisted in using a single sheet of glass, instead of two, as in the one friend Green made; furthermore, in place of a looking-glass for a reflector, a sheet of bright tin was substituted, and the box was painted black so as to absorb as much light as possible, and, in consequence, a proportional amount of heat. The tin, if it would answer the purpose, would be preferable to the glass, as it would be less liable to be broken. One would suppose that these changes, instead of being improvements, would give inferior results; but a careful test of one as thus modified showed 180°. Facts seem to say, One sheet of glass is preferable to two, as any additional thickness of glass absorbs just so much more heat. For this reason, greenhouse men prefer only one thickness of glass. To illustrate further, I took friend Green's extractor into the greenhouse, where there was a summer temperature of 70°. In here, with a summer sun, as it were, I argued in my own mind that the wax-extractor ought to give the same results as if it were outdoors in a hot July day. To my astonishment the thermometer in the extractor, after it had been in the greenhouse for a short time, showed scarcely 170°—somewhat less than that indicated when the extractor was in the open air at a temperature of 50°. Now, while I think that two sheets of glass do not materially lessen the amount of heat, yet, as I see, there is no advantage in having two. The amount of heat lost in radiation from a single sheet is overbalanced by heat lost in absorbtion with two sheets of glass, as already stated.

---

*A cut and description will appear in next GLEANINGS.

The bright tin for a reflector seems to answer every purpose of the looking-glass; besides being cheaper, it will not break.

THE UTILITY OF THESE WAX-EXTRACTORS; BOILING EGGS IN THE SUN.

You notice that we obtained, with the solar wax-extractor, 170 and 180 degrees when the temperature in the open air was only 50°. With a summer heat of 70° outside, if the temperature increases in the extractor proportionately, we ought at least to reach the boiling-point, 212°. According to this, J. A. Green's speculation of eggs boiled in the sun is not so impossible after all. Why, I declare I will coax the "queen clerk" to try her hand at *frying* eggs in the sun when the weather becomes suitable. What fun it would be to run opposition to gasoline stoves? "Steady, young man," some one says; "you are a little premature; besides, the boiling-point is not the frying-point."

"Oh! well, my good friend, if the eggs won't fry, I will say the foregoing is 'a scientific pleasantry,' and that it was Green's notion, not mine;" but, mark you, if the speculation should be a *success*, then I will try to claim a share in the idea; and with as much originality as possible I will say, "I told you so."

THE CONDITION OF OUR BEES UP TO DATE.

The Holy-Land colony that I mentioned on page 90, of this current volume, as being uneasy and showing signs of dysentery, is now dead. All the rest of the colonies are in good condition up to date; and as we have had quite a number of warm spells, they have been breeding quite heavily. The result is, that many have run short of stores, and will have to be given more combs of sealed honey, to prevent starving. I would suggest, as a caution to beginners, when these warm spells in March come, that they would do well to examine all stocks on their summer stands. If they have been breeding heavily as above, and their stores are low, feed them or give them sealed combs of honey.

A little caution now may save you a few colonies later. If the weather is such that the bees are not flying much, I don't think I would tinker with the colonies unless you have good reason to think that some particular swarm is running short of stores.

Two bad months are before us, and so we can't "count our chickens" yet. I will report later.

ERNEST R. ROOT.

USE OF THE THERMOMETER.

HOW IT MAY MISLEAD US IN USING IT IN A BEE-CELLAR.

IN talking about temperature, I want to premise that it is very doubtful if any one can lay down a fixed rule for temperature, that will be safe for all others to follow. If A has fixed upon 45° as the best temperature for his cellar, B may have his bees in different hives, or packed differently, so that, if put in A's cellar, it would be better to have the temperature above or below 45°. Smith and Jones may have their bees exactly alike as to hives and packing, both in equally good condition. Smith says he keeps his at 40°; Jones, at 50°. But the same thermometer, placed alternately in each of the cellars, on one of the central hives, shows that the bees in both cellars are kept at exactly the same temperature. Smith has his thermometer hanging in the coldest spot in his cellar; Jones, in the warmest. Or, the difference may be mainly due to a difference in thermometers, for I have noted a difference of 7 degrees in a lot of thermometers hanging in the same spot in a drugstore.

Of course, it is of value to get the experience of others; but each one must decide for himself at what point his bees keep best, and then, with the same thermometer always hanging in the same place, try to hold steadily at that point.

WARMING AND VENTILATION.

The same means used for warming may aid in ventilation, so the two may well be considered together. In my shop cellar there is no special provision made for ventilation, excepting that a 4-inch stove-pipe runs up through the floor. I don't cite this because I think it's right, but I want to work from facts, and, moreover, there are many who may want to know what to do with just such cellars. The cellar is 18 by 24, on a side hill; a large double door, or, rather, two doors with a 9½-inch air-space between them, leading out on the level on the south side; a small window with double shutters on the west, and one on the east side, and a trap-door overhead. November 10, 124 colonies were put in the cellar. In a few days the bees appeared somewhat uneasy; there was a close, disagreeable smell, and mold was found in spots over the earth floor. A wood fire made in the cellar helped matters, drying it off, and of course the warmer the air the better the ventilation. The heat, however, was very unsteady, and at night the fire would die out entirely, the exit for the air being greatly lessened by the closed stove, and in the morning the thermometer would be down.

About the middle of December I determined on more radical measures. I put in the middle of the cellar a common small cylinder stove for anthracite coal, the inside diameter between the fire-bricks being a little more than eight inches (I also put two in the house cellar). In this I have kept a constant fire, day and night. It makes a steady heat, so little light that I think it does no harm; and the stove-door being always open, makes the best exit for air. The mold has disappeared, the air always smells sweet, and at this writing the bees appear quiet, and are doing nicely. Of course, there is time for them all to die between now and May.

In ordinary weather I find it best to keep the trap-door wide open, the room overhead being darkened; but in very cold weather, every thing is kept shut tight. Once or twice, with the mercury outside below zero, and a strong wind, the cellar has been as low as 36°. With close attention it might have been kept above this. During the last of December we had a warm spell, the outside air going above 40°. At this time I kept doors and windows open at night, and sometimes through the day; but the coal fire was kept steadily going, because, if not needed for heat, it was for ventilation. The hardest time I have found to keep bees quiet has been toward spring, in a cloudy, rainy, damp, warm time. The damp air is so light that it does not, by its weight, force its way into the cellar, and the cellar becomes foul. At such a time, would not a fire in the cellar, even though the bees were already warm enough, make the cellar air lighter, so that the outside air would take its place? My observation leads me toward that belief. A serious objection to heating cellars in this way is the expense and constant care. But where a large number are kept, it may be money and time profitably spent, if thereby the dead-list may be shortened. What I should especially like, however, is some arrangement by which the bees could be placed in the cellar in the fall, and left without any attention till time to take them out in the spring. I have been experimenting a little, and thinking a great deal about sub-ventilation, and had intended to write about it when I commenced this article; but I see I must wait until another time. How do Ira Barber and others keep their cellars so warm? Two of my colonies have starved to death. Poor management!

C. C. MILLER, 179—338.

Marengo, Ill., Feb. 20, 1886.

Friend M., I grant all your points except the ones about the thermometers in the drugstore. If they varied seven degrees, they were a poor lot and ought to have been returned to the maker. Perhaps it was only one or two that were so far out of the mark. In that case I should say they were "out of kilter." See the instructions we give in regard to the use of thermometers, on the one we mail you to-day. And, by the way, it would be an excellent way to test the thermometers, to ask the dealer to show you a dozen. Lay them side by side on the counter; and if they don't all tell the same story within at least two degrees—well, I don't know what would be best to do. Perhaps the charitable way would be to tell him to show you a dozen higher-priced ones; and if the higher-priced ones don't tell the truth better, then I would complain.—It seems to me that keeping a fire all winter long is very expensive business, and I would try to make some automatic arrangement. A reservoir of water warmed up once a day would do it to a dot, if it didn't keep the air too damp; and I am inclined to think that the dampness would do good and not harm. What say you? During this past winter, a reservoir holding perhaps 20 barrels of water, right in the center of our greenhouse, has kept the temperature just as nice as could be, with nothing but sheets of glass intervening between the outdoor air that was 15 degrees below zero. We have not had to get up nights once.

OVERSTOCKING A LOCALITY.

ALSO SOMETHING FROM FRIEND HEDDON IN REGARD TO SUGAR STORES COMPARED WITH NATURAL STORES.

I FEEL that I should publicly thank Prof. Cook for his kind words and friendly criticism, found on page 98. I may as well say it now, even if the Professor does see it, that all through our numerous discussions of subjects upon which we could not agree, I have been compelled to esteem his integrity and judgment as the very highest. I always wish and sometimes dare to hope, that the Professor's opinions regarding "swelling our ranks" are correct; and, as he says in closing his review, that I am "morbid" upon that question, but as yet I can not find the evidence to believe with him as I desire.

I wish it were true that we might multiply the number of honey-producers tenfold; but however much I may desire this, I can not believe that much more increase in our ranks can take place without a suffering on the part of those already engaged. I think I have had letters from five old stalwart producers, in which they have especially complimented the part of the little book that friend Cook believes is over anxiously mistaken.

Another point that seems strange to me is, that some of our bee-keepers, among whom I may mention friend Wright, on the same page, who have never expressed the least fear regarding increasing our product by the increase of producers, are now frightened because some who believe that sugar syrup is superior to honey for winter stores are feeding said syrup, thus causing an increase in the honey supply. Surely, these men must agree with me rather than the Professor regarding the point in question. I think Mr. Wright makes a true statement when he tells us that the sugar we feed increases the market supply of honey, pound for pound, and that the relation between supply and demand governs prices, which means our success or failure.

But right here I think Mr. Wright's argument ends. I know it is natural for any honey-producer to feel just as Mr. Wright does, when he sees his products begging for consumers at a price below cane sugar; and no wonder that his judgment tells him that, before we feed our colonies the higher-priced sugar to take the place of the lower-priced honey, we had better let at least a portion of them die. Such reports as this of Brother Wright's (and they are more numerous than I wish they were) prevent me from believing with friend Cook, however much I may desire. I have bought, sold, and produced comb and extracted honey in a retail, jobbing, and wholesale way, for nearly eighteen years, twelve of which my father has been a wholesale commercial agent, all of which has given me some advantages in gaining a knowledge of the several points made in Mr. Wright's article, and I will give you my opinion regarding a few of them, to be taken for just what it may be considered worth.

First, the cry of "adulteration" has very little tendency to deter purchases of our product. A commodity will usually sell upon its merits, judged by its looks, flavor, and effect. We well remember the wholesale war made against glucose in sugar syrups—how refiners started the cry, which echoed in all the papers of the land; a tumult, compared with which all that has been said regarding adulterated honey might truly be called a faint whisper; and yet you will find, if you take the pains to ascertain, that ever since that time the consumption of commercial syrups has steadily increased. When I began using the extractor, years ago, liquid honey was so novel a thing that its lower price at once gave the impression that "it *must* be adulterated." That was the cry; and the echo of that noise has not died out yet, though I verily believe that it has had no effect in lowering the price nor demand for my honey.

Let us consider the final outcome of "sugar-feeding for winter." Whatever may be true collectively, will not each individual decide the matter for himself? and will that decision not be governed by what he believes to be the best? After making several quite extensive experiments, and talking with others who have done likewise, I am compelled to believe that pure cane-sugar syrup is better than any honey for bees during their period of confinement. If I find that, after all, I am mistaken in this, I shall be eager to announce my discovery, and rejoice that our excellent product is excellent *everywhere.* But let me assure you that it will require something more than desire, or glutted honey markets, to change the opinion that has been compelled by what seems to me to be positive proof. Bee-diarrhea is the condition to be dreaded. It may be called the one cause of our winter troubles. It results from an excessive accumulation of fecal matter. I never saw, and never saw a man who had seen bees that had been confined three months or more upon any kind of natural stores that did not discharge fecal accumulations on their first flight. I confined over 70 colonies for 151 days (five months), at the end of which they flew, with bodies apparently as slim as in autumn, discharg ingnothing, not even water, as far as careful scrutiny could detect. These colonies passed the winter in a cold cellar, where three-fourths of those with natural stores died with bee-diarrhea. Their stores consisted of pure cane-sugar syrup, there not being one drop of honey, or bit of bee-bread, in the combs. I do not think this can be done with natural stores; but if we can bring our bees through their longest periods of confinement upon natural stores, without their accumulating sufficient fecal matter to produce disease, provided we make all other conditions favorable, then I believe that natural stores will finally be our choice. That this can be done, and is done year after year, we have ample evidence; but I doubt that it can be done in all localities, especially my own.

I am giving the matter a critical test this winter; and though I should rejoice to know that the natural stores of my location are safe, one year with another, with all other conditions favorable, yet if I find they are not, I shall also rejoice in the fact that we can give them syrup at the rate of 1000 lbs. per hour (all of which will be taken down within about 24 hours), and that, too, without having to extract any natural stores. JAMES HEDDON.

Dowagiac, Mich.

Friend H., I think it is true that there are some localities somewhat overstocked; but at the same time, there are thousands upon thousands of localities that are not stocked at all, so to speak; therefore let us scatter ourselves, and take up the waste places.—In regard to sugar syrup in place of natural stores, there is one point I forgot to mention, and I tell you it is a grave one. If you go to buying cheap honey to use in lieu of sugar stores, you not only stand a good chance of getting honey that will give the bees dysentery, but you may also give them foul brood; whereas if you go to your grocer and get a barrel of granulated sugar, there is no possibility of any such event. In fact, the sugar feed would go a great way toward banishing the foul brood, after having let the bees consume all the honey. I told you, a month or two ago, that honey was being put upon the market for sale that was extracted from apiaries terribly infested with foul brood. Suppose a bee-keeper gets hold of some of this, and feeds it instead of sugar for winter. Read the following, ye who go on so about sugar feeding:

> You published a piece showing that foul brood was not contagious, and at the bottom consented to it yourself. Well, my neighbor bought foul-brood honey in Cincinnati, and he lost about 40 colonies, and spread it in two of my apiaries. My loss was 12 colonies. The amount of loss in other apiaries is considerable. That much for the diabolical publications. I know several cases of its being contagious. W. F.
>
> Feb. 20, 1886.

I can give the name and address of the writer of the above, if need be, but I think perhaps he wouldn't care to have it published, for he will doubtless set to work and get the foul brood out at once. I need not tell you, that I wrote to him, asking where anybody ever said that foul brood is not contagious, but I have not yet received his reply.

NOTES AND QUERIES.

CONTRACTING BROOD-NEST.

FRIEND Doolittle and others advocate contracting the brood-nest to get section honey. Do they contract the honey-board to the size of the brood-nest, or cover the size of the hive with sections? WM. G. NORTON.

Honeoye Falls, N. Y.

[We believe friend Doolittle practices reducing the room above the cluster by division-boards, whenever the size of the colony makes it necessary, the same way that he contracts the size of the brood-nest.]

THE HONEY PROSPECT IN CALIFORNIA.

The prospects for a honey crop the coming season were never better. Vegetation is unbounded. R. WILKIN.

San Buenaventura, Cal., Feb. 18, 1886.

A DEPTH OF 125 FEET SHOWS 50°.

There being a desire to know the temperature of the earth at different depths from the earth's surface, I made a test of my well, which is 120 feet in depth, made by boring, and inserting a two-inch pipe. The water is drawn by wind power. I let it pump until I was sure the water came from the bottom, then I put a thermometer in a pail and let it pump on it; the mercury stood at fifty degrees above zero. T. S. BULL.

Valparaiso, Ind., Jan. 28, 1886.

WIDE FRAMES AND SEPARATORS.

ARE THEY A CONVENIENCE OR A NUISANCE?

When you said, Mr. Editor, in Gleanings for Jan. 15, page 45, "It is a little amusing to see friend Heddon go back and declare in favor of wide frames, and *separators* also, after the way he has denounced both," I said to myself, "Good! for this will cause Bro. Heddon to explain to us in what manner he has been enabled to overcome the difficulties he once found in the use of them, which was so great that he discarded wide frames, and denounced separators as 'nuisances.'" After thus thinking, imagine my surprise to find W. Z. Hutchinson writing on page 87 of Gleanings, "Can you show, friend Root, where he (Heddon) has harshly denounced wide frames or separators?" and saying, after a search through numerous back volumes of the bee-papers, "I can not find that Mr. Heddon has ever denounced separators."

Well, thought I, can it be that I am so much mistaken? for it can not be that a man who has championed another, as Bro. Hutchinson has friend Heddon, can not know whereof he speaks. It was but the work of a moment for me to turn to page 33 of the *A. B. J.* for 1881, where I find recorded, under the name of James Heddon, these words:

"Separators cost me too great a portion of my surplus crop, to say nothing of their *first* cost and trouble of manipulating."

On page 66 of same volume I find this:

"Separators are better adapted to some supply-dealer who can 'grind' his ax with them" (than for raising comb honey, I suppose is to be inferred).

Again, on page 75, *A. B. J.* for 1881, I read:

"All separators are a great drawback to the production of comb honey."

Then on page 106, these words appear:

"If it is strange that I should declare against the use of *all* separators," etc.; while on page 170 of same volume he says:

"Yes, it is true that we do not need to attach any costly and complicated contrivances (separators) to make our *chosen surplus system* work to our *perfect satisfaction*." (Italics mine in this individual case). By again referring to page 33, I read:

"There is no need of the nuisances called separators," which I am sure is a *harsh denunciation*, if none of the rest can be so construed.

What think you, Bro. Hutchinson? Now, I have not written this altogether to prove that Bro. Hutchinson made a mistake, and that friend Root was right, but mainly for the purpose of drawing Bro. Heddon out, so that he will tell us wherein he has remedied the defective system of separators, so that he has gone from the calling of them "nuisances," to using and recommending them to others. If, as he says, they cost him "too great a portion of his surplus crop," how has he brought it about so that now they cost him none of it? and if "all separators are a great drawback to the production of comb honey," what special plans has he adopted regarding separators, so that this drawback has been overcome? These questions are of vital importance to us; and if Bro. Heddon has no secrets in the matter we should like to have him explain. I have always used separators in the same way Bro. H. now does in his new hive, and called them a convenience rather than a "nuisance;" and if there is any knowledge to be gained whereby I can add to my crop of surplus honey, I am interested to gain it. Now about wide frames.

On page 170 of *A. B. J.* for 1881, Bro. Heddon says, "The reason I discarded the broad (wide) frame system was because the sections were so stuck up with propolis;" while on page 100 of present volume of Gleanings he says, "I was driven from their (wide frames) use, as well as the hundreds who went with me, from our experience with them in two-story supers." Now, Bro. H., which of these reasons is right? If the latter, you have told us how you overcome the objection to "two-story supers;" but if the former, you have not told us how you overcame the propolis question. Of course, you have in some way, for this propolis question has been raging for years, and I am sure you would not leave your case system, which was so *free from propolis*, and go to using the wide-frame system, without overcoming this defect. Propolis on sections is a nuisance, be the same little or much; and a plan which will allow of the filling of the sections with nice comb honey, without changing the clean appearance which they present when placed upon the hive, will be heralded with delight by all, and give great honor to him who works out the plan. Surely none of us can object to any one changing his plans as often as occasion requires; but in doing so it is well to say that previous views were mistaken ones, or else give to the public how our former objections have been overcome. When friend Betsinger invented wide frames in connection with separators, to be used one tier high, he gave us one of the greatest conveniences regarding the production of comb honey; and Bro. Heddon's going back to these is one of the best parts to his new system of management. G. M. Doolittle.

Borodino, N. Y., Feb. 13, 1886.

SOMETHING FURTHER ON THE TEMPERANCE QUESTION.

IS LICENSE OR TAXATION TO BE CONSIDERED AT ALL?

If you have no objections, I will offer a few words in reply to Prof. Cook, on page 47. He says: "Why will not a law like that adopted in some of the States suit all, do more good, and get the support of all temperance people? That is, a license with a heavy fee in conjunction, with local option in every *town*, *village*, or *city* where it can be carried?"

A right to grant a license implies a right to withhold it; hence a license law which does not compel the granting of licenses is in effect a local-option law. Whether the option should be exercised by States, by counties, or by towns, is the question. Prof. Cook says by *towns*, *villages*, and *cities*, and for a high price. This is just what we have now, and have always had in Wisconsin. But this is far from being a model temperance State, though the price of a license is not less than two hundred dollars. The amount paid is a direct *bribe* paid to the village for the privilege of cursing the community.

Our village of M. has about 1000 inhabitants. It collects for liquor-licenses, two thousand dollars annually; four-fifths of that amount is paid into the village treasury through the saloons by the surrounding agricultural towns. In return for this, the agricultural interests are taxed to support the paupers and prosecute the criminals, made such by this worse than useless traffic. If this monstrous evil must be licensed, I insist that all income from such licenses should be paid over to the county, and applied to the support of the poor or the prosecution of criminals. If all license fees were paid into the county treasury it would take away from villages the chief inducements to grant licenses. If we had local option by counties instead of by towns, many counties would prohibit, and, step by step, prohibition might be accomplished everywhere.

I have great respect for Prof. Cook and his many valuable articles on other subjects; and if he had not asked the influence of GLEANINGS for his plan, I would not have tried to state mine. Nothing short of total prohibition will satisfy me.

Mauston, Wis., Feb., 1886. F. WILCOX.

Now, friends, I think we shall have to let the matter of temperance rest where it is for the present. I am sure the readers of GLEANINGS are all in favor of stopping the liquor-traffic; and although we may differ widely in regard to the means to be employed, can we not hold ourselves, all of us, in readiness to push ahead wherever God seems to point the way?

CHAFF HIVES WITH ONLY EIGHT FRAMES INSTEAD OF TEN.

WHAT THICKNESS OF PACKING IS NECESSARY, ETC.?

WHY not make chaff hives to take eight frames instead of ten, somewhat after the Falcon style? Use a Simplicity hive if you want sections in wide frames; but I think cases will take the lead for holding sections. Have the hive tall enough, with the cover, to hold two or three sets of $4\frac{1}{4}$ sections. We could have the ends of hive permanently chaff-packed, and one side too, if that would be best. There are some points in the Falcon hive that I think would suit me better than the Simplicity chaff hive; but I think both of them are too large. I think six L. combs are enough to winter any ordinary colony of bees on; and then if we had eight-frame hives we should have enough combs to take care of.

I can't see the use in having a hive as large as the Simplicity chaff hive. I understand they have only three inches of chaff. Now, if we have three or four inches of chaff at the sides, and nine inches for the combs to winter the bees in, we should not have such a very large hive. Then have one side of the packing, or both, for that matter, movable, to put in the other two or more combs in the spring, or as they are needed. I have made up my mind that chaff hives are the cheapest in the long run, for this country, though I have had very good success wintering in the Simplicity (my style) for several years. Last winter I lost by starvation, dysentery, and queenlessness, 7 colonies out of 26, and that was by far the heaviest loss I ever had. I should think two inches of chaff would be enough for the ends of the hive, and three or four at the sides.

I have three colonies of bees in Simplicity chaff hives. I just put them in this fall, therefore I am not prepared to say how I shall like them. I am thinking of making chaff hives for next year, but am at a stand about what to get. J. S. WILLARD.

Bedford, Taylor Co., Iowa, Dec. 30, 1885.

Friend W., an eight-frame chaff hive would answer nicely, without doubt; but it would be making another style of hives for our catalogues and price lists, for it wouldn't work with the implements and appliances already in use for the ten-frame hives, and would in many respects complicate matters more than they are already complicated. Your bees would also be more liable to starve, if you make the brood-nest smaller. I think it will be far better to use division-boards to reduce the space at such seasons of the year as we wish the space reduced.

SOLAR WAX-EXTRACTORS.

PREVENTING AFTER-SWARMS, ETC.

I SEE on page 776, Nov. 15, 1885, you ask how many of the friends have used the solar wax-extractor. I have one I made this summer. It is a box 20 in. wide by 30 long by 12 deep. I put a false bottom in the middle, about 24 in. long. I got a sheet of tin 20×28, cut off two corners of the tin at an angle, then turned up the edge one inch all around, except the two inches in the center of the lower end; nailed a rim around one end and the sides of the box, with two saw-cuts about $\frac{3}{4}$ in. apart, and slipped in, from the open end, two lights of glass, 20×30, or lights 15×20; then close up the end, putting in a pan on the bottom. Your wax on the tin now drips on the raised bottom. Set it on the south side of the house, inclined to give what slant you want, and in a very short time, with the outside heat up to about 70° (I think it was) the wax will all be melted. You want to look out and not take out some of the refuse with your fingers, or you may shake them as badly as I did. If I were to make another one I would make the sides flaring; and would not a black iron dripping-pan draw more heat in there than the bright tin? You want the thing made so no current of air can pass through. It makes the nicest wax I ever saw.

Our honey crop out this way is very slim this year—only 660 lbs. from about 30 colonies in spring, and a little more than that of extracted. I like the Heddon way of preventing after-swarms, first-rate.

SOME QUESTIONS IN REGARD TO THE CARE OF STEAM-ENGINES.

I want to know if a steam-engine and boiler corrode, rust out, and become worthless, about as quick if it is not used more than two or three months in the year, as it would if it were used and cared for properly the whole time? What causes the boiler to explode when the water gets too low? Is there any book on the engine, telling how to run and take care of them? V. W. KEENEY.

Shirland, Ill., Nov. 23, 1885.

Friend K., we like the solar wax-extractor too, and I was greatly astonished to find that the heat of the sun was ample, even in the middle of February, and we made some of the nicest wax with it that I have ever seen. There is no trouble in getting heat enough. Perhaps a pan made of black iron might do better than a tin one. We will try to test the matter by experiment.—It depends upon who runs the engine. If it were properly fixed to lie idle, I think I should prefer to have it so; but if it were dropped right where it was last used, and no pains taken to prevent rust and damage, I would rather have it in constant use. If I am correct, letting the water get low does not cause the boiler to *explode*. It does. however, draw the flues out of shape, and cause the boiler to be sure to explode, if the engineer is so thoughtless as to pump water into it when red-hot. If, however, he finds he has by accident boiled all the water out, and heated the flues red-hot, he can just let the fires go down, and no harm is done. When the flues get cold, he may even go on with his work, if the boiler does not leak so badly as to put the fire out. Explosions are generally caused by pumping water on to red-hot flues. This results in making a great volume of steam so suddenly that the safety-valve is entirely inadequate to carry it off, so that everything is blown to pieces with an explosion. I do not know of any book on the care of the steam-engine—at least, nothing up to modern times. If any of our readers know of such a work, I should be glad to put it in our book list.

EGG-LAYING OF QUEENS.

IS IT THE BEES OR THE QUEENS, OR THE SIZE OF THE CELLS THAT DETERMINES THE SEX?

I READ with much interest the able article from the pen of Mr. Chas. Dadant, as I always do any thing from him. Mr. Dadant's statement, that the use of worker comb, or worker foundation, almost wholly precludes the deposition of drone-eggs, and therefore the presence of drone-brood, is certainly a thoroughly well-established fact, and is one of the strong arguments in favor of the use of foundation. Yet, does this fact necessarily lead to Mr. Dadant's conclusion, "A queen in good health lays drone-eggs in drone-cells, because they are greater; and worker-eggs in worker-cells, because they are smaller"? If, as I think, the queen knows what she is about, and acts from volition, then surely she would not lay the unfecundated egg in a cell that would restrict the size and full development of the drones, or male bees. I think the queen knows the large cells are for drones, and will lay the unfecundated eggs in no other, except by mistake. The fact as I gave it before, that very short worker-cells, hardly deeper than those of our best foundation, sometimes receive eggs that develop into workers, as no doubt Mr. Dadant has witnessed, is very significant; and can any one doubt, after examination, that the queen lays the egg in the queen-cells? But, if any other proof were needed we have it at our command: In some species, like *A. Indica*, the drones are smaller than the workers; while in wasps, like *Vespa vulgaris*, the cells are all equally large; yet the whole life economy of the *Vespa* and *Apis* genera, so far as reproduction is concerned, are identical. Our ants, too, closely related to bees in many respects, produce males and females in the same manner as do bees, and their eggs are not placed in cells at all.

Mr. Dadant's point, that the reason why young queens lay some drone-eggs in worker-cells is because the queen is small, and so her abdomen is not compressed, would surely have weight if it stood alone. Yet, were this the case I should suppose there would be more drones. They are usually very few and scattering. In my apiary I have once in a while had a very small queen, hardly larger, though slimmer, than a common worker, even in her most fecund days; yet her eggs in worker-cells produced workers. Has not Mr. Dadant noticed the same? So I still think these young queens at first fail to manage adroitly the muscular machinery that extrudes the sperm-cells from the spermatheca.

Mr. Dadant's conclusions as to wasps are not warranted, I think. The wasps that Sir John Lubbock referred to are our mud-wasps, not our paper-making wasps. These mud-wasps do vary the size of the cells—those containing the males being the smaller. So the point Mr. Dadant makes is hardly warranted, I think, by the facts in the case.

Do animals drop eggs at just such a time, irrespective of surroundings? I doubt it. Some of our birds that usually lay only five eggs will continue to lay as many as thirty, if we keep taking the egg from the nest. Thus, a flicker, *Colaptes auratus*, laid over thirty under these circumstances, here on our college campus.

From all these facts, I still think the queen knows what she is about, and that fecundation of the egg is voluntary, not automatic.

I wish to express my pleasure, that Messrs. Dadant & Son are revising Mr. Langstroth's book. I think he could not have chosen more wisely.

Agricultural College, Mich. A. J. COOK.

Friends Cook and Dadant, may I now put in a thought which I believe neither of you have touched upon? It is this: That the worker-bees are a factor, as well as the queen, in deciding whether they will raise drones or workers. You may remember, that some years ago there was a discussion in regard to the swarming impulse. Does the queen lead out the swarm, or do the bees? Several brought forth very clear facts to show that it was the queen that went out, and that the bees followed her. Others brought equally plain facts to show that the bees got up the excitement and poured out of the hive, and finally the queen joined in and went with them. But we were finally forced to conclude that it was sometimes the one and sometimes the other; or, most likely, the queen and bees both acting in perfect harmony.—Now for A. I. Root's theory about determining the sex. I suggest that the bees have the power, at least very largely, in their own hands, so to speak. I have tried in vain to get early drones, by placing the drone-comb in the center of the brood-nest. The queen would not occupy these drone-cells until other queens in other hives began rearing drones also. If I fed the colony, the bees used this drone-comb for storing honey; and it has just occurred to me that the queen didn't lay any eggs in the drone-comb, because the bees did not fix the cells, and invite her to occupy them. Is it not true, that a queen never occupies any cell, drone or worker, until the bees first clean it out, varnish it over, and give it that fresh, inviting appearance, with which we are all so familiar? Are we sure that they do not say by actions, if not by words, "When your highness gets that little patch of comb filled, please come over here and take these next"? Who has not tried to get a queen to fill combs when the cluster of bees was so small they couldn't get cells ready for her fast enough? She would fill all the cells that were properly prepared, and then, instead of going over to those nice clean worker-cells the bees hadn't glossed over and puttered with, would either stand around idly, or else go over the cells again, where she had just deposited eggs, putting two or more in a cell, and worrying the owner so much that he would be prompted to write a letter to A. I. Root about it, and ask if he hadn't better pinch her head off, when the queen was just as good a queen as could be, with only a pound of bees or a little more.

"THE OTHER SIDE" OF FLORIDA.

TWELVE MONTHS IN FLORIDA.

I SEE you publish a great many letters in favor of Florida. I send you a letter I got from the Charlottesville *Chronicle*. It looks at Florida on "the other side." HARRY GRIFFIN.

Charlottesville, Va., Jan. 7, 1886.

Editor Chronicle: — Hearing that a good many citizens of this section are considering the expediency of emigrating to the "Land of Flowers," probably persuaded thereto by the flowery pamphlets and maps so industriously circulated by the railroad and land companies; and, actuated by a desire to save those contemplating such a step from the disappointment almost sure to result, I send you the substance of some notes taken "on the spot."

In the first place, the much-lauded climate is a most unmitigated fraud—to a native of Piedmont, Virginia. Thermometers are "no good" there. They lie winter and summer. It is more disagreeably cold when 32° F. is indicated than when the mercury falls to zero here; and the almost vertical rays of the midsummer sun are so intensely hot and so thoroughly enervating that the most energetic man becomes willing to do nothing but pine for his mountain home again. My observation is that they embrace the first opportunity of getting out of a Florida summer, devoutly promising themselves not to be caught again. The thermometer may not indicate more than 90° F. when it oppresses one as much as 105° F. here.

The soil, in the greater portion of the State, is no soil at all, but a vast sand-bank, with a slight admixture of humus, which is exhausted by a crop or two. It is necessary to fertilize well every year to obtain a good crop. Frequent wide expanses of swamp and thousands of bogs and ponds detract from the value, and add nothing to the beauty of the country. While there are some fair lands, termed "hammocks," they are generally so infested with insects, and so unhealthy, that it is unwise to live near them. *Lovely*, they certainly are, with each twig and limb fringed with Spanish moss, which often droops many feet and gracefully sweeps to every breeze. But, amidst the tropical beauties of the scene, malaria insidiously lurks, ready to seize upon the casual intruder upon his native haunts. Except the veritable hills, the whole State lies *under water* during the rainy season.

As to products: Nearly every one who goes to Florida has the *orange craze*, and forthwith falls a prey to one of the legion of land agents, who will often palm off on the innocent an admirable location—for a duck farm! Every one is saving orange seed, planting orange seed, setting out orange-groves, millions and tens of millions of orange-trees! While many will die from frost or some mismanagement, yet it is patent that the business is overdone, and the profit in orange groves falls to the land speculator who sells off "choice" (?) lots at ridiculously fancy prices.

The lemon, being more easily killed by frost than the orange, can be profitably grown in few localities in the State; for the "line of no frost," so much dwelt upon in the effusions of general passenger agents, must be set down as a bare myth, frost being seen and *felt* in all parts of the State. In the more southern sections, pineapples, bananas, Japan persimmons, cocoanuts, are being profitably raised. But those who go to those parts must expect to see mosquitos by the quintillions, and carry a trunk full of quinine to ward off chills.

Market gardening, now rapidly assuming large proportions, is *the* future business of Florida. The lands require heavy fertilizing, and the crops are occasionally nipped by those "unheard of" frosts, yet the early products bring such fabulous prices that the business is, beyond doubt, the most promising in the State.

In conclusion, while money can be and is made in the ways mentioned, the intending emigrant from Piedmont, Virginia, should remember that he will have to contend against such ills and pests — unknown here—as will try his patient soul though he be a very Job. As surely as he tries orange-growing in Florida, he will concede that, if the same attention were given our pippin-orchards as is necessary to be paid to orange-groves, the pippin-orchards would be the more profitable. And as surely as he spends a year in that much-boomed sand-bank will he further concede that he was a fool to leave this goodly heritage of land and clime, and be ready to swear that, if Fate kindly permits him once more to see his "own, his native land," he will never, *no, never*! NO, NEVER! seek "Eldorado"—"Land of Flowers!" or thirst for the "Fountain of Eternal Youth." JAY C. ELL.

Why, friend G., I do not think the letter is such a bad one, after all. It is probably a very fair and candid statement of the way the average Northern citizen would look at things when there. And there is one point I want to call special attention to. If the same attention were given to our pippin-orchards right close about us, that they are obliged to give orange-groves in Florida, to get even an average crop, what sort of pippins should we have? Friend Cole, in his book, tells what the effect was on an old worthless apple-tree on a hillside by giving the ground around it (and under it) intelligent culture.

A WHOLE APIARY OF HIVES WITHOUT BOTTOM-BOARDS.

IS IT NOT AN ADVANTAGE TO USE HIVES WITHOUT BOTTOM-BOARDS?

IN GLEANINGS, Nov. 15, page 793, I notice where you say a hive which Conrad Weckesser mentions is a novelty. Now, I wish to state that one of the most successful box-hive men I have ever heard of in Texas does not use a bottom-board at all, and he keeps from 60 to 100 colonies of bees all the time, and has kept them for years. His name is J. M. Bell, of Winnton, Gonzales Co., Texas. He simply places a block about 2 inches square and an inch thick under each corner, to keep the hive from settling into the ground in wet weather. In wintering he moves the hive about its width to one side (so as to get a clean place, and get all trash that may have accumulated during the summer, outside the hive), and banks the earth up to the hive all around, leaving for a winter entrance two ¾-inch auger-holes, previously bored into the hive about 3 inches from the bottom edge of the box. I tried some box hives myself the last season, and I find that if the hive is open on all sides underneath, that the bees seldom lie out in our warmest weather (and I assure you we have weather warm enough to melt beeswax, and make it run like oil). I am going to try a lot of Simplicity bodies, without bottom, in the way mentioned above, the coming season, as it will be quite a saving in the way of labor and material, if we can get along without a bottom-board. Of course, this plan will work well only on a sandy slope where the ground will drain and keep washed clean. I happen to own just such a place, so you see I am favorably located for the experiment. I will report to

GLEANINGS in due time the result of my experiments, when you will be able to judge for yourself whether the plan is a good one or not.

REVERSIBLE FRAMES.

Speaking of reversible hives, page 771, Nov. 15, why not use the Quinby closed-end frame, and use no outside shell at all for the hive, but simply fasten the required number of frames together with a clamp, and when you want to reverse just turn the whole thing bottom up? M. BROERS, 20.

Gonzales, Texas.

Friend B., instead of having the whole bottom of the hive open, I would suggest that it be contracted; and if this contraction be done so as to make a sort of hopper below, at the same time it lets in the air, it will tumble out all the dead bees that drop down from any of the combs. When I first invented the Simplicity hive, I suggested that they could be set on four half-bricks, without any bottom-board; bank up the sides to keep out robbers, and to keep out too much of a draft of air when the weather is cold. I have had very good success with working hives in the summer with nothing but the ground for a bottom.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER III.

FAMILY TALKS ON BEES, CONTINUED.

ANOTHER day at dinner, Mr. Meek said: "If your bees live until spring, and then swarm, hives will be needed in which to hive your swarms. It is now an important question to decide what kind of a hive you will adopt. Bee-keepers tell me it is a great advantage to have all the hives in an apiary of exactly the same size and pattern, and to use on all the same kind of fixtures for obtaining honey. It is very annoying to the keeper of a large apiary to have a great variety of hives and fixtures. I would merely say, that now, as you are making a beginning, be sure you make a *right* beginning."

Jane replied, "The great difficulty I see is, the firm has no money with which to purchase hives, and therefore I think we shall be compelled to hunt up old boxes and kegs for hives, as Mr. Brown does. As I have been reading about bees, I have learned about several things we shall need, and I have been wondering how we shall obtain money to buy them."

"I know very well," said her father, "you can not buy without money; but if you and Tommy keep up your interest in your apiary, I will lend you what money you need, and will wait on you until you have honey to sell. I will do so, not because I approve of going in debt, but because I desire the firm to start in business right, and I see you can not do that without some money. Therefore I will lend you money to buy whatever I feel will be needed. Now let us decide what kind of a hive we shall use."

Tommy then gave his views. "I did think we could use nail-kegs for hives. I think we can get them for nothing. Then I thought we would call our apiary the 'Nail-Keg Apiary;' but lately I have thought I should like nicely painted hives. I want a hive from which we can take honey without killing the bees. I guess we can not do that with nail-kegs. Besides, nail-kegs are not very pretty bee-hives."

Here Jane asked her father, "What are movable-frame hives? In both the book and magazines I read much about them, and it seems all bee-keepers are using them; but I do not know what they are."

Mr. Meek replied, "I am glad you asked that question, because movable-frame hives are the kind I prefer, and the kind I want the firm to use. Bee-keepers often want to open their hives and examine them, or they would like to take a comb filled with honey or young bees from one hive, and give it to another. In the old-fashioned box hives they could not do this. At length some men who had given much study to bee culture conceived the idea of compelling the bees to build each comb in a neat little frame. We can handle that picture on the wall easily, because that and the glass protecting it are held securely in a frame. Suppose that, instead of that picture, there were a comb of honey in that frame, we could handle it as easily as the picture and glass. Bee-men now have all their combs built in frames, and such hives are called movable-frame hives."

Mrs. Meek here asked, "Are these frames any advantage to the bees?"

Her husband replied, "No. The bees would prefer a clean empty box to a box filled with frames; and if a person does not intend to handle the frames, it is a needless expense and trouble to have them. A mere box would be cheaper, and would suit just as well. Now, do you expect to handle your frames?"

"Oh, yes," said Tommy.

His mother laughed, and said, "Wait, Master Tommy, until you receive a few stings, and see how you stand them, before you talk about opening a bee-hive and taking out the frames."

"But, mother," said Jane, "I have been reading in Mr. Langstroth's book, and also in the magazines, that we can quiet bees by blowing smoke upon them; and I also learned that we can buy a little instrument for this purpose, called a bellows smoker, which is very useful to any one handling bees. I suppose the smoke makes them stupid."

Mr. Meek said, "That is not the reason. A bee that is full of honey is not apt to sting, unless hurt. They have an instinctive dread of fire. When the smoke is blown among them they seem to think, 'Our house is on fire and will be burned up, honey and all, and we be turned out to hunt up another. We must save all we can;' so each bee runs to where there is some honey and fills its honey-sac, and thus becomes good-natured. If you close a hive and drum on it, the same result takes place. The bees think from the noise, 'Our home is being pulled to pieces; we shall surely be robbed;' and so each bee loads up, saying, 'We shall at least save all we can carry.' As you have been reading Langstroth's book, and hence know something about his hive, I think you had best adopt it. When in town one day last summer I saw Mr. Woods, a carpenter, making Langstroth hives for sale, and I think the best plan would be to buy some hives of him. When Tommy is older I think he might make his own hives; but I do not think he could at present. As you have only the one hive to provide for, we need not buy any thing for next summer until spring, and we see that our bees are all right. Have you any more questions to ask me?"

Jane replied, "Please tell us something about comb foundation. I have been reading about it in the magazines, but I do not understand exactly what it is."

Mr. Meek then gave a description of comb foundation. He said, "Wax is not something bees gather, but it is something manufactured in their bodies. It is much more costly than honey. It is thought that a colony may eat twenty pounds of honey to secure one pound of wax. Bee-men tried many ways to enable bees to use a second time the wax they had once made. The only way they could do this was by carefully preserving the old combs, and fitting them into frames. Even the small fragments were carefully fitted into frames. These the bees mended, making nice strong combs; but if these were once melted down into wax, the bees would not make any further use of that wax. At length comb foundation was invented, and by its use bees are led to accept old wax, and work it over. Comb foundation is made in this way: You take a nice smooth board, the size you want your sheets of foundation. Soak it full of water, then have a can of melted beeswax, into which dip this wet board, and a thin sheet of wax will adhere to the board, which, when cool, will slip off. In this way you obtain your thin sheets of wax. The commencements of the cells are then made on these sheets of wax, by machines invented for that purpose. Comb foundation, then, is merely wax sheets on which are the commencements of the cells. Bee-men think it pays to use foundation. The foundation used in the boxes must be very thin."

Tommy asked if it would be necessary to buy a machine and wax, and make this foundation. His father replied, "No, you can buy the foundation already made; and I advise you to buy some thin foundation for your honey-boxes; and, speaking of boxes, leads me to ask what kind of boxes you will use. This is an important matter. You know Mr. Brown obtains his surplus honey in all kinds of boxes. When he sells any honey he takes one or two of these large boxes to a store. Customers seldom want to buy at once as much honey as they contain, therefore the storekeeper cuts out chunks to suit them. This involves waste from the honey that leaks out, and makes such a muss in handling it that the storekeeper does not care to buy when Mr. Brown comes with another large box. It was thought, What an advantage it would be if surplus honey could be built in frames, like the combs in the lower story! hence the section box has been invented; that is, a box not all fastened together, but in sections. Suppose I take some lath and make six frames from it, say five by six inches in size. If they are neatly made, and of exactly the same size, they can be pressed together, with two end-boards, and will make a box that can easily be taken into six pieces. Now, if I could have each little frame filled with a comb of honey, they could be handled without any trouble. At present these little frames or section boxes are used by all bee-keepers who make a success of raising comb honey. These little frames do not cost much; and as they sell by weight with the honey, they do not really cost any thing. You must also purchase some little boxes or frames to hold these section boxes in place in the hives; and if you want straight nice combs in the little frames you will have to purchase strips of tin, called separators, to use between the sections. These section boxes are of different sizes. The most common sizes are those holding one and two pounds."

By talks such as these, the children were daily learning more and more about bee culture, besides what they learned from reading on the subject. But about this time their school opened for the winter term; and as they both attended, their minds were occupied about their studies and plays, and for a time bee culture did not receive so much attention from them. Still, they and their father frequently talked on the subject. When it became evident that winter had set in, Mr. Meek carried the hive into the cellar, and, placing it in a dark corner, inverted an empty barrel over it, so the light might not arouse them when Mrs. Meek or any of the family entered the cellar with a lamp. The cellar in winter was very dark and quite warm, being fitted for keeping vegetables. The bees could not suffer from cold, and it was hoped that all other conditions would prove favorable to their wintering successfully.

To be continued April 1.

CARNIOLANS: HOW THEY PLEASE OVER IN IRELAND.

A CROSS OF THESE BEES WITH BLACKS, NOT "CROSS."

EARLY in 1884 I ordered two Carniolan queens from Messrs. George Neighbour & Sons, of London, England, to be delivered about the end of May; but the first did not come to hand until June 19th. She was large, and of a mahogany-red color, and arrived in splendid condition. Her attendants were very much more numerous than I had ever seen with foreign queens, and there were only two dead bees in the box. Immediately on her arrival she was introduced to a strong stock (from which the former queen had just been removed), by caging her on one of the combs, and her bees were united to those in the hive. Next day she was released, and the day after she began to lay; but what struck me as very unusual was her remaining on the comb on which she had been caged for ten days after her release. I say this because I opened the hive daily, and always found her on the same comb, even after she had deposited an egg in every vacant cell on it, and I could not find any trace of eggs in any of the other combs, most of which had, in the meantime, become pretty well filled with honey. Becoming impatient at her want of attention to business, I took her by the wings and placed her on a comb at the end of the hive, after which her conduct was every thing that could be desired. As the honey-flow was over for the season before the Carniolan bees were out, I could not speak of them as honey-gatherers; but the queen bred rapidly, and the stock went into winter quarters very strong in bees.

The second queen did not arrive for several days after the first one; and when she did come I was not so well pleased with her. Although she was very large, and light in color, she was out of condition. I got her safely introduced to a strong stock, in which she did very well for a time; but about a month after her introduction I was standing in front of her hive when I saw her crawl out and fall to the ground in a dying state. I opened the hive and found numerous queen-cells, from one of which a queen hatched in due course. She was one of the smallest and darkest queens I ever saw, but she proved to be very prolific. I saw her all right when packing the stock for winter; but she disappeared mysteriously, and the hive was queenless when I looked at it the following spring.

The first stock came out of winter quarters in very fine condition, and throve amazingly. I moved it into a twenty-frame hive (the largest I had), but I could not get the bees to work in sections, whether placed in the body of the hive or over the frames, so I put a second story on the hive, with excluder lying between, for extracting, and the rate at which those bees brought in honey was simply astonishing. About the end of June, 1885, a swarm issued from this stock; but the bees, after clustering, returned without the old queen. I fancy she must have fallen to the ground and got lost, for I never saw her again.

My opinion of the Carniolans is, that they are the best bees we have. The queens are conspicuous, the bees are gentle, and good honey-gatherers, and they are very hardy. I think them quite as handsome as the Italians, Cyprians, or Syrians, none of which are good honey-gatherers in this country. To show the industry of the Carniolans, I may mention that I sometimes feed my stock by placing a supply of syrup outdoors at some little distance from the hives. The Carniolans are the first to find it out, and have every drop taken away before the blacks begin flying for the day.

Although the Carniolans do not stay on the combs as well as the Italians, they are much more easily handled than the blacks. The crosses, first, second, and third, with blacks, are almost as gentle as the full bloods, which is a consideration when introducing new blood into an apiary. I intend to get half a dozen queens next season; and if you will allow me, I shall write to you again to let you know how they go on. I think Carniolans would be more generally kept but for the difficulty in getting queens early in the season. Last year, for instance, I ordered some queens, to be delivered in May, but I could not hear any thing about them until August, when I was advised that *one* had arrived.

Dublin, Ireland. ROBERT SPROULE.

We are very glad indeed, friend S., to get so good a report from the Carniolans, and shall be quite glad to hear from you again on the subject. They will have a careful test in our own apiary this coming season, nothing preventing.

KIND WORDS.

SOMETHING TO THE CREDIT SIDE OF HUMANITY.

I ONCE before remarked, that it was not altogether people who are owing you that won't write letters, for very often we find those who have a *credit* on our books neglect to answer. Once a year we go over the credits and send statements. When a man does not reply after we have sent him one statement, asking him if his credit is correct, we write to his postmaster to see if he has moved away, or is dead, or something of that sort. A great many times it turns out that he meant to answer all the while, but kept putting it off. Now, we don't care how long money is left in our hands—in fact, we always prefer to pay interest where the sum amounts to any thing; but we like to know that it is all right, and that the rightful owner may clearly understand that he can have it any time he wants it. Well, the friend who writes below happened to be the postmaster himself, and here is his reply:

My Dear Mr. Root:—Your letter of the first inst. was received, and in reply I would say I have been postmaster so long I almost forget the time when I was not. Your other two letters were received. The reason I did not answer them was on account of my wanting again, some time, some more of your stock. It gives me pleasure to think there is one man in this whole United States who is anxious to do as he would like to be done by. You will hear from me again in the future. With many thanks I remain yours. G. W. GILLITS.

Ellington, Ia., Feb. 4, 1886.

Is it not worth while to get such a letter as the above?

HOUSE-APIARIES.

RECONSIDERED BY W. F. CLARKE.

AT all our conventions much useful information is gained by conversation with that quiet class of bee-keepers who have never outgrown the habit of modest childhood, but still make it a rule to speak only when they are spoken to. In fact, the lobby meetings are often more interesting and instructive than the public ones. The recent Detroit Convention furnished many illustrations of the truth of these remarks. Among the topics much discussed "betweenwhiles" was that of house-apiaries. The stillest man in the convention was perhaps the most talkative on this theme out of it. I refer to Mr. J. Vandervoort, who has become a thorough believer in house apiaries, and could "a tale unfold" in regard to them that would interest the dullest convention ever assembled. But, unfortunately, Mr. Vandervoort is no talker in public, though he is one of the best I ever listened to in private. He is a good writer, however; and if he would write out his views and experiences on house-apiaries he would confer a great benefit on the bee-keeping public.

The house-apiary is not a new idea, by any means, but one that has been tried in various forms for more than a century past. Most of those who have tried it for a time have abandoned it because of some objection or difficulty which might, with patient thought, have been obviated. From the window at which I am writing I have a full view of a pretty little house-apiary which I built more than twenty years ago, and abandoned after a single year's trial of it. I found it objectionable, because the house appeared to be practically one hive; and if a single colony became excited, all the neighbors joined in the row; also, because the entrances, being exactly alike, young queens were apt to enter the wrong hive when returning from their wedding-tour. Another difficulty was, that the place became unbearably hot when the blazing beams of the summer sun shone remorselessly down upon it. But these objections, as may be readily perceived, are by no means insuperable ones.

New reasons having presented themselves to my mind of late for thinking it desirable that hives should be housed, I have been studying the subject very carefully, and was in a position to appreciate Mr. Vandervoort's views as expressed in conversation at Detroit. The more I investigate and reflect on the matter, the more persuaded I feel that the next great step in advance to be taken in practical bee-keeping is the construction of houses which shall be permanent homes for the honey-bees during both winter and summer, and then good-by to three-fourths of the worry and trouble now connected with putting hives into winter quarters and taking them out again.

I have been reading the A B C article on house-apiaries; and, really, the arguments in their favor therein adduced are so numerous and cogent that I wonder they have not commanded more attention from bee-keepers. But, if my memory does not mislead me, these arguments have been, to a great extent, nullified by unfavorable opinions expressed in GLEANINGS since the A B C book was published. I think, too, the great objection urged in GLEANINGS as fatal to the idea of house-apiaries was, that multitudes of bees would get into the house and could not be gotten out of it back into their respective hives again. If so, this is a notable example of a difficulty which requires only a little thought, and a very simple device, in order to its removal. Have the house totally dark, with the exception of a little door just above the hive being operated upon. Bees always fly for the light; and there being none except what is admitted by the aperture close to their own hive, they will quickly go outside the hive, and hover about the entrance to their own particular hive until quietness is restored, when they will at once betake themselves to their own domicile.

Mr. Editor, if you will kindly republish, along with this article, a couple of cuts and a communication which appeared in GLEANINGS for May, 1882, it will obviate the necessity for my saying more at this time. The cuts and remarks give a complete description of "Oliver Foster's house-apiary," which is the simplest, cheapest, and most practical thing of the kind with which I have met. I think, too, it is almost a fac-simile of the house-apiary now used by Mr. Vandervoort, and of which he speaks in the warmest terms of commendation.

By the way, Mr. Editor, you said in your foot-note to Mr. Foster's communication, "I feel very much inclined to make just such a house-apiary now, and I rather think I shall like it." Did you do so? and if you did, with what results? Your experience, if you have had any in the actual working of that plan, would be opportune and valuable just at this juncture, when many of us are revolving the matter in our minds, and meditating the erection of a house apiary of some kind when spring comes.

Guelph, Ont., Feb. 5, 1886. WM. F. CLARKE.

Friend C., there are certainly many very good reasons why house-apiaries should not be abandoned. I, too, had a long talk with friend Vandervoort in regard to his house-apiaries, and the way in which he succeeds in getting large crops of honey from them. When we returned from New Orleans we rode a long distance with him, and discussed the matter pretty thoroughly. I tried to take down some figures in regard to his large yields, but didn't get them. If I am correct, he promised to write the matter up for us, but I think he has never done so. You propose to obviate my great objection by having the house totally dark, with the exception of a little door above the hive being operated upon. This necessitates a little door that will open and shut over every hive in the house-apiary—an item of no small expense, you will notice. The next question is, "Will it do the work when you get it done?" Coe's house-apiary, you may remember, was guaranteed to do this very thing. I rode forty miles on purpose to see it, and to see him do this little trick with several others. The house was darkened completely; the little door was opened, and it was near the floor too, so as to give the bees every chance to fly or crawl out. At my suggestion, some bees were shaken off on to the floor, at a little distance from this door. Did they go for the daylight at once, and all get off from the floor? Not at all. They did just as I expected they would—they went out when they got ready. But we had to go out of the building, and come back after a while, before they went back. If I mistake not, some of the young bees didn't go back, even then. I have tried all of these things thoroughly; and it is so much more bother and trouble, compared with hives outdoors, that no one I have ever seen yet likes house-apiaries, unless it is for raising comb honey. Keeping the floor clean is one great obstacle with us; and if I were to build another, there should be no floor—just the ground as it is outdoors; then if a bee is stepped on and mashed, you have not got to scrub to make things look decent again. So far as securing the honey is concerned, I believe I could get more honey in the house-apiary than in hives outdoors. In regard to the intolerable heat, somebody suggested making a house apiary like a corn-crib so that it would have nearly as much circulation as all outdoors. The man who made it, however, afterward reported that it didn't answer at all. Since wire cloth is so cheap, it might be a little better inducement. If you make it bee-proof, however, you are going to have trouble with the bees inside, that can not get out as before; and if you *don't* make it bee-proof, you must look out for robbers as you would if every thing were outdoors. Friend Vandervoort, I believe, raises his queens in the hives outdoors, and arranges every thing expressly for the production of comb honey. Before reproducing the article from Oliver Foster, we should like to have him tell us how it answers by this time.

SALT, A NECESSARY ELEMENT FOR BEES.

SALT FOR BEES; AN EXPLANATION OF THE REASON WHY BEES GATHER MUD OR DRY EARTH.

As I have often observed, and studied for several years the phenomenon described by John W. Niman, pages 9 and 10, 1886, I will give what light I have on the subject. I have, with one exception, always found bees sucking clay, as described, either in roads, barn-yards, and other places containing the excrement of animals, or the drainage therefrom, and hence I soon concluded that it was some constituent of this that they were seeking; but exactly what that was, I did not know. Happily, about two years ago an accident enabled me, as I think, to solve this. It became necessary for me to move my meat-house from where it had stood for about 30 years, and thus I exposed a little plot of ground that was filled with salt. My bees immediately took to it, as I had seen them in the above-described places. I saw that their reason for preferring the ridges and points was that, being more exposed, the evaporation was greatest there, and hence there was more salt deposited, or its solution made stronger. Now, as salt is the only thing likely to be found in all such places, and to fill all the requirements of the facts, I think salt is the element the bees were carrying to their hives; and with your permission, I will compound a new word for bee-keepers, and call such places "bee-licks." Further, I want to call the attention of bee-keepers, and emphasize the remark of friend Niman, in regard to what the bees were carrying in, "The want of it may be the cause of disease." W. H. GREER.

Paris, Tenn., Jan. 18, 1886.

Friend G., I shouldn't be surprised if you had hit the secret of this strange conduct of the bees. Further investigation, however, will be necessary to decide the matter. The fondness that bees many times exhibit for salt has been several times gone over in our past volumes. Of late, I notice that the poultry-journals are deciding that poultry must have salt in small quantities, or they will pluck out each other's feathers, etc. Now, let us see to it that our bees have a bee-lick near the apiary, where they can at all times help themselves. A glass jar of salt water over one of the grooved boards we advertise will, I think, be about the right thing. May be some sawdust around the jar would please them better, for I have seen them fairly burrow in sawdust where salt brine had been poured out on it.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

We respectfully solicit the aid of our friends in conducting this department, and would consider it a favor to have them send us all circulars that have a deceptive appearance. The greatest care will be at all times maintained to prevent injustice being done any one.

THE GOLDEN BEE-HIVE.

A FEW days ago I saw an agent of the Golden bee-hive. He argued in favor of the Golden, while I was in favor of the Simplicity hives. At this time I use neither of the kind mentioned. The agent said to me that A. I. Root had abandoned the Simplicity, and was using the Golden exclusively. He attempted to produce a paper to that effect, but afterward said he did not have it with him, but would show it to me at another time. I concluded to write and hear from you at once, before I saw him again, to know if such be the fact. F. A. PARSONS.

Oconee, Wash. Co., Ga., Feb. 10, 1886.

Friend P., the patent-right man is trying to come the old trick over you. I have never seen a Golden bee-hive in my life, but we have published the agents as humbugs and swindlers for years past. We use the Simplicity hive for a summer hive entirely, just as we have done for the past thirteen years. The chaff hive is the same thing exactly, inside, and takes the same frame. It is better protected from winter's frosts and summer's heat.

THE BOHEMIAN-OAT SWINDLE, AND THE WAY THE AUTHORITIES ARE BEGINNING TO HANDLE IT.

The following we clip from the Medina *Democrat:*

A Bohemian-oats trial was recently held in Ohio, where a man sued some parties who sold Bohemian oats. He brought suit to recover the money, and won the case. He received damages in the sum of $200, and interest on the same for one year. Good decision.

We extract the following from the Cincinnati *Commercial Gazette:*

WEST SONORA, O., January 28.—A new bait in the Bohemian oats is some kind of new-fangled wheat, and it is sold at the same modest price of ten dollars per bushel, the farmer receiving a contract that his entire crop will be purchased from him in one year at $7.50 per bushel. Few persons have any conception of the gigantic extent of the Bohemian-oats swindle in Preble County. About $75,000 worth of notes have been given by Preble County farmers for the Bohemian oats. Most of the purchasers knew that the venture was risky, and a good deal in the nature of a swindle, but many thought the bubble would not burst for two or three years, or else they could bulldoze their money out of the agents without much difficulty. So in they went, and now they are rushing frantically around trying to get a small per cent of their money back.

It behooves us as citizens of Ohio to try to clear off this slur from the reputation of our State, for it seems that this swindle was first inaugurated here. It seems to me that notices like the above ought to be sufficient to wind up the Bohemian oats, not only in Ohio, but in every other State.

THE RASPBERRY.

FURTHER FACTS, CONCLUDED FROM PAGE 668.

SOIL.

A DEEP rich upland clay loam is preferable, but the raspberry can be grown successfully on about any soil that is worth planting to corn, and the number of bushels of Gregg raspberries which can be grown on a piece of land will compare favorably with the number of bushels of corn that could be obtained from the same land. In the spring of 1881 we set 500 Gregg plants on a piece of rather thin gravelly land which had been in corn the previous season; and without applying any fertilizers to either the corn or raspberry-plants we have gathered four crops of berries, and have a growth of canes for next year which ought to yield at the rate of thirty or forty bushels per acre.

PREPARATION OF LAND.

The land should be plowed and harrowed as for potatoes or corn, and then "run out" three or four inches deep, in rows six or seven feet apart; or it may be "run out" in rows three or three and a half feet apart, and potatoes, sweet corn, or something of that sort, planted in alternate rows, with the berry-plants the first year. During the first year, and especially at the time of planting, six feet seems like entirely too much room between the rows; but the man who puts the rows much closer will be pretty sure to regret it in two years. The plants should be set about three feet apart in the rows.

CULTIVATION.

The cultivation which the raspberry should have is not different, especially during the first year, from what corn ought to have; and the implements commonly used in corn culture, with possibly the exception of those plows which work both sides of a row at once, are suitable for the raspberry-patch. We have not used any thing but the hoe and the common double-shovel plow—going over the plantation once with the former, and about three times with the latter each year. In the first year it may be necessary to use the cultivator as late as August, but after the first year we have not cultivated later than the latter part of June. While deep cultivation close to the plants will doubtless be injurious by destroying and mutilating many of the roots, we feel sure that moderately deep cultivation at a little distance from the plants has not injured our plantation.

PRUNING BLACK CAPS.

When the young plant is set in autumn or early spring, it has no top except a few inches of the old cane from which it was propagated; but in due time it will send up one or more young shoots; and when these have attained a height of from 12 to 18 inches we pinch out the tops. This pinching-out of the tops stops the upward growth, and causes the plant to throw out several laterals; and in the following March these laterals are cut back to from 10 to 20 inches in length. This pinching-out of the tops in summer (about the first of June), and cutting back of the laterals the next spring together, after the first year, with the cutting-out of the worn-out dead canes, which may be removed either directly after the fruit has been gathered from them, or at the time of the regular pruning the next spring, is the amount of pruning required to keep the plantation in nice order. A child ten years old can pinch out the tops in summer, and a girl of twelve years did the work of cutting back the laterals on one acre last spring. I think a good active man can cut back the laterals, cut out the old dead canes, carry out and burn the rubbish of an acre, in about three days.

GATHERING THE FRUIT.

Berries should not be picked when wet with dew or rain. They should be picked without being mashed, and put into quart baskets as picked, and the baskets should be free from unripe or imperfect berries and leaves; they should contain nothing but dry, ripe clean fruit. In the summer of 1885 we had one girl who could, under favorable circumstances, pick 100 qts. in a day; but her best average for a week was 62 qts. The price of picking is one and a half to two cents per qt., the pickers boarding themselves. In this section of country the selling price of berries during the past season ranged from 15 cts. to 6¼ cts. per qt. The bulk of the crop sold at much nearer the latter than the former.

YIELD OF HONEY.

I don't know how much honey the bees can get from an acre of Gregg raspberries, but I know that for ten or more days, about the last of May and first of June, they just swarm over the raspberry-patch from early in the morning till late in the evening. The Gregg raspberry blooms with the locust, and the honey gathered from these two sources is a superior article, both in color and in flavor; and some that I extracted June 7, 1884, has not yet candied.

I live in a farming community, at a considerable distance from the railroad, and from large towns. No one about here thought of buying berries, or of growing them for sale, and I supposed that I should have to evaporate mine and send them to market that way. Now for the result. Last summer we sold about 100 bushels to persons who came to the yard after them, and some days it took nearly half of my time to explain to would-be customers that it was impossible to let them have berries. Some of the men near Steubenville pick and sell about 100 bushels a day.

In conclusion, I wish to say that it will not pay to write to me about plants. I have none to sell.

E. Springfield, O., Jan. 26. R. M. REYNOLDS.

Why, friend R., you almost take our breath away. As many bushels of raspberries to the acre as farmers get bushels of corn, and the raspberries are worth about three or four dollars a bushel, while the corn is worth thirty or forty cents! The trouble is, however, that men who raise corn, for some reason or other could not or would not raise raspberries. I am astonished again to know that you found a home market for 100 bushels of raspberries. This is a good deal like establishing a home market for comb honey in many places. The facts you give us are very valuable indeed; but it still seems to me that ground that will grow corn will not always grow raspberries. Raspberry culture has been tried a number of times in our vicinity, but they always grow up to weeds after a little while, and things get back in the old channel. One thing I can tell you, however, the Gregg raspberries on *our* honey-farm are not going to grow up to weeds. If you have not any plants to sell, and more customers for your berries than you can possibly supply, the most uncharitable of our readers won't think you are an interested party in giving us these facts. Another thing, this business of berry culture furnishes so much employment for the boys and girls. A girl or boy who earns money, and buys what he needs with the money thus earned, is smarter and brighter, and ahead in every respect, of those who live along some way without employment. Now, then, for the berries and honey. Who will have a berry-patch this very spring?

SOME OF A BEGINNER'S EXPERIENCE.

SEPARATORS OR NO SEPARATORS.

I HAVE had a few swarms of bees for twenty years, in different kinds of hives, with but little knowledge of how to manage them. About one year ago I thought I would try to see what I could learn about keeping bees. Mrs. Lizzie Cotton's circular came to hand about this time. I sent for her book on bee-keeping. I had a hive made according to her plan, but I did not like it. Next was Quinby's book on bee-keeping, which was very good, but I did not fancy his hive. I next saw your advertisement, I think in the *American Agriculturist*. I sent for a catalogue, then the A B C, and then for GLEANINGS. I believe I struck the right track. I ordered from A. I. Root 10 chaff and 10 Simplicity hives, and went to work with a will. I had six colonies in different kinds of hives.

In the spring of 1885, as soon as the weather was warm enough I commenced to transfer. I transferred them into Simplicity hives. About the middle of June they commenced swarming, and each hive sent out three swarms. I hived them all but one. The fountain pump I ordered of you is "just splendid." I could drive them in any direction by throwing a spray into their front ranks. The one that left was a third swarm, and with all the water thrown on them they did not stop. They did not even stop to cluster. The new swarms in new hives worked well, and I think I have learned something, but still I feel that I am a dull scholar, for I did not put any starters in my nice metal-cornered frames, and before I was aware of it the bees had built them crooked, and joined them so I could not lift them out of some of the hives. One of the first swarms sent out a swarm. One made 30 lbs. of honey in 1-lb. sections; two others made about 10 lbs. each. This surplus honey was all made in crates in chaff hives. For a number of years, honey has been exhibited at our county fair, so I thought I would show our shipping-crate filled with 1-lb. sections. Each section was filled out, all propolis was scraped off the sections, and placed in the crate. Having had separators between them when they were filled, they were straight, and all the sections looked alike. Each section could be lifted out with ease. I placed the crate on the table near two other lots of honey that had been left there for the premium. The other two lots were in a rough box with glass in one side, all nailed up, but one could see the 1-lb. sections through the glass—the same kind of sections mine were—and as nice-looking honey as mine, but they did not use separators between the sections, and consequently they were irregular, with some broken honey-comb. Mine was taken out, section after section, and turned over and over, and no sign of any breakage. I was in the hall but a very little while, but I told those in charge to let every one examine it all they wished to. One man asked me if that honey was for sale. I told him he could have it, and another and another. The other two lots were carried home. I wanted to take mine home, but it was too good to keep.

The most difficult problem I find in bee-keeping is how to make bees store surplus honey in boxes. Last summer I had one swarm which sent out three swarms, and stored 15 lbs. of surplus in boxes, while others, just as strong, stored no honey in surplus-boxes. L. N. CHAPMAN.

River Falls, Wis., Jan. 12, 1886.

HOW TO PUT UP AND SHIP BEES BY THE POUND.

OLIVER FOSTER'S METHOD.

AS it has been requested in GLEANINGS, I will give a description of my method of putting up and shipping bees by the pound, with some "reasons why." In his foot-notes on page 66, the editor says: "But we wanted to know how Mr. Foster puts up bees without any brood or comb," etc.

By referring to my circular you will see that I do not sell bees that way; nor can I see any advantage, either to shipper or buyer, in depriving the little fellows of their cherished young during shipment; but there are some grave disadvantages to all concerned. In early spring, when most shipments are made, every good queen (and we would have no others), will keep her hive supplied with all the brood that her bees can possibly cover and provide for. Now take a pound or more of bees without brood, from such a colony, and the result will be more or less of chilled or half-starved brood, which means a filthy mass for the remaining bees to remove, or dwarfed and feeble bees for the next customer.

If the brood is divided between the other colonies, this only divides the difficulty and makes extra work. As for the bees confined for shipment, we do not claim that they really mourn the loss of their little ones as animals of a higher order do, but every experienced bee-keeper has noticed the salutary influence that the presence of brood, especially unsealed brood, has over a colony in almost any condition.

This influence shows its power for good when "the little busy bee," born peculiarly for liberty, is consciously imprisoned in a shipping-box. It is also very important, when the bees are liberated in their new home, to have some of their brood with them, as, after a long journey, they may abscond without it. Also if the colony is obliged to begin at the "foot of the ladder," without brood, instead of increasing from the first they must naturally decrease in numbers until their brood hatches, which will be at least three weeks. The dealer should make it to the buyer's interest to get some brood with his bees.

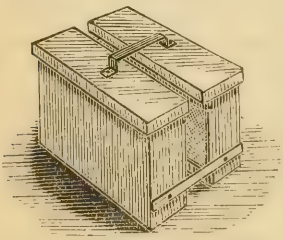
As for stores for shipping-cages, I claim that sealed clover or basswood honey is the *cheapest*, *safest*, and *best* food for bees in summer or winter, in freedom or in confinement; and the lightest and most perfect receptacle for these stores is the comb in which it was originally stored. Sufficient stores are usually found in the combs containing the brood to supply bees and brood during their trip. If not, a small block of sealed honey is placed on edge against the side of the box on one lower corner, and the comb is then pressed tight against it and fastened. If there is too much honey, part should be extracted, to save express charges. Before describing my shipping-box, we will notice one more point.

We have all seen bees worrying on the inside of a window. Their instinct seems to tell them, in a general way, that they can go wherever they can see, so they will worry themselves to death in a few hours, trying to fly through a pane of glass. If we lean a board against the outside of the window they will not try to get through opposite the board. If the window is of wire cloth instead of glass, and if the room in which they are confined is only a shipping-box, the delusion is much the same, and it is *worry* that kills most bees in shipping. I know there is a vast difference in bees as well as in persons about worrying; but the best way to get along with either is to always "stroke the right way of the fur."

HOW MY SHIPPING-BOXES ARE MADE.

My shipping-boxes are all made of thin lumber, mostly 5-16 inch thick. For colonies of 5 or 6 lbs. of bees I use boxes about the size of the Simplicity hive. Wire cloth is tacked over the bottom, and a movable wire-cloth cover slips over the top, trunk-lid fashion. The covers are fastened down by two pieces of hoop iron, one at each end passing across from cover to box, and fastened to each with screws. These covers are provided with strong handles by which the whole box can be easily handled with one hand.

To raise the bottom off the floor, and to protect the wire from being broken, a cleat, one inch square, is nailed across each end over the wire, and a thin bottom is nailed to these cleats, which leaves a one-inch space below the wire, open at each side. For smaller colonies I use boxes like the above, but only half as wide. These will do for 5 lbs. of bees, if only one or two combs of brood are put in. To hold the combs in place, I use spacing-sticks ½ inch square and 8 inches long. A one-inch wire nail is driven through, ⅛ inch from one end, so that the point projects ¼ inch. These sticks are placed between the ends of the frames, so that the point of the nail rests on the top of one frame, and the head on the other. When the sticks are in place, the frames are crowded together, and the outside one is fastened with wire nails.



OLIVER FOSTER'S SHIPPING-CASE.

Most of my orders are for packages of one pound of bees, one or two combs of brood and a queen. For these I use boxes just wide enough for two combs. As these fall over so easily when single, I fasten two or three together, where several are ordered; and instead of having wire on the top and bottom, I have it on one side only. To fasten the boxes together, a piece of strap iron is placed across, from box to box, at each end near the bottom, and bolted to the boxes, leaving a two-inch space between the boxes. A hoop-iron handle is then fastened across the top, being bolted at the ends to the middle of each cover. This also holds the boxes in place at the top. These bolts are 3-16 × 1 inch, with a round slotted head, and they are fastened permanently in the covers and end-boards with the heads inside. To keep the bolts from turning, I drive a one-inch wire nail part way in, near the end of the slot, then bend it over into the slot, and clinch the point on the other side. As the nuts turn easily with the fingers, the boxes can be taken apart and put together quickly without tools. Bees will ship safely in these if properly put up. Most of my boxes have been returned to me free by express. Our agent recently referred the question to the Supt. of the American Express Co. His reply was, that bee-boxes do not come under the head of "empties," to be returned free. If bee-dealers would adopt a standard shipping-box, something light, strong, and handy, as mine are, I think the express companies could be persuaded to return them free, as they do other empties.

10—OLIVER FOSTER, 250—296.

Mt. Vernon, Iowa, Jan. 25, 1886.

Friend Foster, your points in favor of a comb of brood, instead of sending a pound of bees without any brood or combs, are well taken, and I grant every one of them. But, may I say there is something to be said on the other side? And as this is a very important matter indeed, I hope I shall be excused for going over ground that has been several times gone over already. Your comb of brood is worth a good deal to you; and if you send it, you have to get your pay some way. Perhaps I should add, that we do not have brood die for want of bees to cover it. We always have more or less colonies having many bees and little or no brood. This comes from selling off queens, and waiting for new ones to lay, so there is hardly ever a time in our apiary when we can not place a frame of brood of any age where it will prove a blessing to the bees that receive it, and not an egg nor larva will be lost. Now, we find those blocks filled with Good candy very much cheaper, and easier to handle, than a frame of brood. Second, a great many of our purchasers don't want a frame of our combs, because the frames will not fit their hives. A large part of our trade, for instance, is with those who have lost their bees in wintering. They have empty hives and empty combs. They want queens and bees, but they don't want our kind of frame nor our combs. Another thing, a great many bee-keepers have a choice queen, with so small a cluster of bees in the spring, that, if she pulls through, she will be little if any profit; whereas a pound of young Italians, or even half a pound, would set her right on her feet, so to speak. Some hatching brood might do very well, but she is already able to furnish more eggs ten times than her bees can *possibly* take care of. In such a case, only *bees* are wanted. If bee-keepers could be made to come down to a standard frame, so that the frames used by one party would be sure to fit nicely the hive used by another party, it would be a grand thing, and right in line with your plan. We also furnish brood-combs where wanted and paid for, as you may recollect; and where we send as many as three or four pounds of bees, we prefer to furnish stores in a frame of comb with some brood. But I should say that nine out of ten of our orders are for one-half or a whole pound of bees without any brood, and, a great many times, without any queen. But while I think of it, I believe that bees without a queen always ship better if a little piece of brood is given them. Your suggestions in regard to covering the bees so that not much light strikes them, is a good one. I am anticipating a great deal of pleasure in shipping bees in a single section of Heddon's new hive.

REPORTS ENCOURAGING.

50 COLONIES, AND 2500 LBS. OF HONEY; THE RELATIVE GOOD POINTS OF BLACKS AND ITALIANS.

I THOUGHT I would send my report. I commenced this spring with 50 colonies; got 2500 lbs. of honey—500 extracted, and the rest comb. The extracted was all sold at home at from 12½ to 15 cts. About half of the comb honey was sold at 17 to 20 cts. It will be five years next April since I commenced bee-keeping. I have had Italians with the black bees all this time, and I have been trying to find out which are the best. I have got my bees pretty well mixed, from pure Italian to black. I think the difference is not so much in the bees as what they get honey from. I think the black bees will get the most honey from raspberries. They are about equal on white clover. The Italians are the best on basswood; the blacks are the best on buckwheat. The Italians are the best on thistles; they are about equal on goldenrod. This will show you how hard it is for me to decide, as basswood is from two to three miles away, and doesn't blossom every year. As to the handling, it will depend on what we work them for. You can get more honey from black bees in one day, than from the Italians.

Portville, N. Y. F. ROULO.

FROM 37 TO 74, AND $320 IN MONEY.

In the spring of 1885 I purchased 37 colonies of black bees, in Quinby-frame hives. I increased to 74 by natural swarming, and worked them all for comb honey, in one to two lb. sections. I received from honey sales, $230; for 20 swarms sold, $90. I put 53 in cellar, Dec. 1; six were light and one uneasy, with bees dying. Jan. 10th I set them on a clean bottom-board, and they seem to be more quiet now. Cellar temperature ranges from 40 to 45°. I fixed the Heddon plan for preventing afterswarms, and it worked well with me.

Depeyster, N. Y., Feb. 14, 1886. FRED C. CLARK.

MY REPORT—A B C CLASS.

I started in the spring of 1884 with one colony of black bees; divided them, and for my trouble I received many stings and no honey. I packed them in forest-leaves, and they came through the severe winter in fine condition. I fed them about 20 lbs. of damaged sugar in the spring, to stimulate the queens, with fair success, I think, for a beginner, as I have taken 175 lbs. of fine comb honey. I increased from two to six colonies, all Italians. My honey pays all expenses, and I have my bees for profit, which I value at $50.00. JOHN S. SCOVEN.

Kokomo, Ind.

A MILD WINTER.

Our bees are amusing themselves by robbing each other this warm weather. We have not had more than one day at a time when they did not fly out. We are having a very mild winter. We commenced this spring with 22, and increased to 60. We extracted 4004 lbs., and got 346 lbs. of comb honey.

Church Hill, Miss., Dec. 30, 1885. WM. BOLES.

FALSE STATEMENTS IN REGARD TO THE HONEY BUSINESS OF OUR COUNTRY.

As a protection to our bee-keeping population, we propose in this department to publish the names of newspapers that persist in publishing false statements in regard to the purity of honey which we as bee-keepers put on the market.

Thou shalt not bear false witness against thy neighbor.—Ex. 20: 16.

WE are pleased to see the *Farm and Fireside* come out fairly and honestly and own up that the charges against bee-men and comb honey are false, as in the following:

> Notwithstanding all the stories to the contrary that have been floating in the press, comb honey has never been counterfeited.

By the way, I am very glad to be able to say that the New York *Witness* published promptly the remonstrance which I sent them. As you may wish to have it copied in your own papers I give it below, as it appeared in the *Witness* of Jan. 28:

> NO ADULTERATION IN HONEY.
>
> *To the Editors and Readers of the Witness:*
>
> May I ask space to say that no such thing as manufactured comb honey has yet appeared in the market of New York city, or any other market in the world? and so well am I satisfied that the whole thing is an utter impossibility, and ever will be, that I will willingly spend $1000 in hunting up the establishment where such an article is made, if it be made anywhere. I choose to speak thus strongly because of the statements appearing in the *Witness* and other papers to the effect that our comb honey is spurious, some papers even going so far as to say that neither the comb itself nor its contents ever came from a bee-hive. Liquid honey may be adulterated, and no doubt is to some extent; but as the quality of honey gathered by the bees varies greatly, ranging from a grade of honey so poor that no one would want to eat it, all the way up to our finest clover and basswood and mountain-sage honey, it is nothing strange that the public denounce as spurious a good deal that may have been put on the market. Let us fight down frauds, and insist that goods be labeled truthfully and honestly; but let us be careful about declaring that comb honey and "hens' eggs" are manufactured by machinery. We bee-keepers will try to make due allowance for pleasantry, and for the fondness of our American people for something new and wonderful; but please remember, dear friends, that what is fun for you is often death to us. A. I. ROOT,
>
> Editor of GLEANINGS IN BEE CULTURE.
>
> Medina, O., Jan. 28, 1885.

Now, if any paper that has unwittingly given place to these sensational statements will give us a hearing by publishing the above, or any thing similar, of course nothing further is to be desired; and we can recommend the *Rural New-Yorker*, *Prairie Farmer*, *Farm and Fireside*, and the *Witness*. We shall be glad to give the names of all other papers that seem disposed to grant us a hearing.

The *A. B. J.* comes down heavily upon religious papers that have published these statements, damaging to our industry, and are slow to correct the mischief they have done. Friend Newman says they are breaking the ninth commandment, which was "thundered from Sinai"—"Thou shalt not bear false witness against thy neighbor." We are sorry to see that the N. Y. *Tribune* still sticks to the "fraud" part of the business. They copy the following, apparently by way of indorsement, from the *Central Baptist*:

> Glucose adulterates our sugar, syrup, jellies, and preserves, and now it seems we have honey-comb filled with it. Some day the laws against adulteration of food will be explicit enough to reach these rascals.

Yes, dear friends of the *Tribune*, I do hope the laws will some day be explicit enough to reach such rascals, and the rascals as well who break the ninth commandment.

Later.—The following is just at hand, from Robert West, editor of the Chicago *Advance*, so we have one more paper to add to our list of those who are willing to give us a hearing:

> *A. I. Root, Esq., Dear Sir:*—Your very kind letter came when I was too ill to reply to it. Your communication we gladly publish next week. Thanking you for the spirit of your criticisms, as well as for your letter, and assuring you that truth in the matter is what I seek, I am yours truly,
>
> Chicago, Ill., Feb. 16, 1886. ROBERT WEST.

In conclusion, I am frank to admit that I have been greatly disposed to show a want of charity in this matter, and I hereby beg pardon for being hasty in regard to the *Advance* and *Witness*.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

TESTING EXTRACTED HONEY.

AN inquiry has been made by a friend, who uses honey as a medicine, and he wishes to use it pure. How can extracted honey be tested, to discover any adulteration that may have been made? Probably you would be pleased to notice this inquiry in GLEANINGS.

Elkhart, Ind., Feb. 11, 1886. J. S. COFFMAN.

Friend C., there is no way that can be laid down in books and journals for testing extracted honey, that I know of, that wouldn't be expensive and rather impracticable. You can test the presence of cheap glucose by sweetening a cup of tea with a teaspoonful of the honey. If it contains glucose, it will make the tea black. A few days ago some milk was left in a tin dish, from which the tin was worn off so as to expose the iron. As soon as the milk was poured into the tea, the mixture looked like ink. The tannin contained in the tea makes a delicate test for the presence of iron. If the quality of the glucose, however, were very good, there would be no trace of iron about it, so the test is by no means infallible. To get a chemist to test honey usually costs from five to ten dollars, and he may make a mistake, even then. I do not see any better way than to buy your honey of some reliable firm, or get it with the name of the producer on the package. Certainly not one bee-keeper in a thousand would put his name on a package of honey that was not pure. A good many samples of honey have been sent me since our late discussion in the matter, but I am quite certain that all that have been sent me have been absolutely pure honey, made by the bees, although some of it is very poor in quality.

YELLOW WASPS, AN ENEMY TO THE MOTH MILLER.

Last spring, as I had no place to keep the combs from the hives in which the bees died during the winter, I hung four or five in a hive, and placed five or six hives, one on top of the other, with a bottom-board between each hive. I had six such tiers. When I used them in June and July I found thousands of the wings and legs of the bee-miller under each hive, and but five or six moths in the whole lot of combs. A nest of very large yellow wasps, or hornets, had taken possession of one of the hives, and filled three of the combs nearly full of brood. They got so strong that I had to burn them. I think there was three pints of those big yellow fellows after I had got them killed. A strange part of this freak is, that in a short time after I had killed the ugly "varmen," what combs were left became so full of moth worms that I had to remove them to a safe place, and brimstone them. Now, what I should like to know is, did the wasps kill all these millers? If not, what did? At any rate, they spoiled three combs for me, as the bees would not clean the wasps' brood out of them. WM. L. KING.

Sodus, Berrien Co., Mich.

Friend K., your remarks remind us of what L. L. Langstroth recently wrote in regard to spiders as a protector of empty combs. The yellow wasps, without doubt, decided that the larvæ of the moth were just the thing to feed their young, and probably did a thriving business, as the quantity of brood you mention attests. You give us another strange fact; and that is, that these wasps will use combs built by bees. Why did you kill the wasps? Why not let the wasps' brood hatch out itself, and then your combs would have been as good as ever?

WHAT IS SPHAGNUM MOSS? AND SOMETHING ABOUT WHERE TO GET IT.

Please tell what sphagnum moss is. Is it the kind that grows on old logs, in low ground?

The Bend, Defiance Co., O. F. W. MOATS.

Why, friend M., it is the kind of moss you refer to, but I suppose any sort of moss would do for making seeds grow, on the plan given by Mr. Henderson. We get ours from a peat swamp that we underdrained last fall, for the privilege of drawing away as much peat as we wanted. We spade up the moss in great chunks as big as a man can lift. It is then dried over our steam-boiler, when it is rubbed through the hands until fine, and then sifted over the seeds. We have formerly got sphagnum from florists and from nurserymen in the cities; but the kind we get from our own swamp here at home works nicer than any we can purchase.

SOME WISE COUNSELS FROM CUBA.

I feel like thanking G. M. Doolittle for his article on page 13, "Few or many Colonies: which?" and I do not know that I should slight you for the remarks you make upon his article. If the beginners could be made to understand that success in bee-keeping does not so much depend upon the number of colonies as upon the amount of honey secured from a few colonies when the range is not overstocked, there would be more satisfaction and better-filled pocket-books. Let's have no more colonies than our range will support, and lots of bees in each colony. A. W. OSBURN.

Havana, Cuba, Jan. 22, 1886.

MARKING A BEE WITH PAINT.

I see in your last issue that you suggest putting a drop of white paint on the back of bees to mark them, so as to see how long they would live after their sting has been removed. I would say, that oil of any kind, put on to a bee or other insect, will kill it in half a minute, as it gets into the breathing-pores and strangles it. C. C. MILES.

Des Moines, Ia., Jan. 22, 1886.

So says theory, friend M., but the facts do not agree. A little bit of thick paint on the fur of the bee's body does not hurt him, as several have proved. One friend let the paint run through a crack in the roof of the hive while he was painting it, and, without trying to, he marked several of the bees; and, strange to say, the queen was among them.

HOW TO GET SPIDER-PLANT SEEDS TO GROW EVERY TIME.

It is natural for all wild-plant seeds to lie in the ground and freeze through the winter. We must follow nature if we want them to grow. You want to plant, or, rather, bury the seeds, in the winter. Take a small bag, put the seeds in it, and bury it in the ground one or two inches deep, where they will freeze during the winter; and after the ground is done freezing in early spring, prepare a good rich bed, make it in rows one or two feet apart, then go to where you buried your seeds and take them up, and they will all be sprouted. Take them, and plant and cover with loose rich dirt, and every seed will be sure to grow with no more trouble, except to transplant when large enough.

Parrish, Ill., Dec. 14, 1885. MOLLIE DIXON.

We have sometimes thought that freezing the seed was an advantage; at any rate, we know that freezing does not hurt the seed, because the spider plant is a great plant to come up of its own accord wherever it is sown the season before. We now get any sort of plants to grow by simply sowing the seed, by the plan recommended in our issue for Jan. 15, page 62, for raising seeds for vegetable plants. We are going to try some spider plants this year over those reservoirs. Two or three feet of heavily manured soil, with water underneath it, ought to do something stupendous with the spider plant.

WHAT IS THE PROCESS OF PACKING PORK WITH HONEY?

Again I am notified my time has expired with the old year. You ask me if I have found GLEANINGS a good investment? I have, and I have learned more by reading it than any other paper I take—not only about bees, but about other matters in Home readings, "What to Do," etc. What you said about the convention gave me new ideas and some good advice. As using honey for packing pork is something new to me, please give your readers the process, or how to use it in packing pork, etc. My wife uses honey in place of sugar in making cake, etc. I for one like it; that is, when we have it. As to bees, I have only two hives. They are doing well thus far. I. R. GREEN.

Unadilla, Otsego Co., N. Y., Dec. 28, 1885.

Friend G., I do not know the process of packing pork with honey, only that the honey is made to take the place of sugar and molasses. Perhaps the substitution of honey where sugar and molasses are called for in the recipes for making pork pickle is all that is requred. Doubtless friend Muth can enlighten us.

IS IT POSSIBLE TO GET EVEN GOOD-LOOKING HONEY BY SUGAR FEEDING, AND AT A PRICE WHERE IT COULD COMPETE WITH REAL HONEY?

After reading Mrs. Harrison's revelation and Mrs. Wright's protest, I expected the editor would take up the gauntlet and hurl back such a volume of evidence as would prove, for all time to come, that sugar can not be fed to bees, and get it stored in sections, not even to get partly filled sections completed; but he didn't "rile," worth a cent. Now, why is this? Has some person demonstrated that it can be done, and we wish to keep the matter as quiet as possible, or are we all halting between two opinions? I have a notion to put (not before the house, as the house is too slow), but to the editors of all the bee-journals, and it is this: That they appoint an investigating committee, to be composed of a number of the prominent bee-keepers of the country, and request them to experiment and prove whether sugar can or can not be fed to bees, and have them build comb, and store it in the sections in paying quantites, or in any quantity. If such is the case, then the grumblers have the long end of the lever; but if it is impossible, and Mr. Wright is aware of the fact, he can easily convince those merchants that his honey is pure, by offering them a fair price for all the honey they can secure in that way. Even if honey can be procured by feeding, and it takes 1½ lbs. of 8-cent sugar to produce 1 lb. of honey, he would yet be safe in offering to pay a fair price for a large quantity, if there is any way of detecting the difference. Now, if I am not mistaken we need more light on this subject.

Brock, Neb., Feb. 13, 1886. J. S. JOHNSTON.

Why, my good friend Johnston, we had the answer to this question on page 101, where friend Unterkircher fed back 3500 lbs., and it did not half pay expenses. Surely, feeding sugar wouldn't give any better results, would it?

BEE STING POISON AS A REMEDY FOR RHEUMATISM.

We take the following from the *British Bee Journal* of Jan. 21:

> *El Siglio Medico* relates the following singular case, which may prove interesting to the bee-keeping world:
>
> A woman had suffered so much from rheumatism that for six months she had hardly slept. Her right arm was so affected that it was quite useless; she could neither work with it, nor dress herself. While in this state she heard of a countryman who suffered in the same way, and who had been cured by the accidental sting of a bee. As the pain caused by the sting could not be worse than that due to the rheumatism she determined to try the same remedy. Three bees were obtained and made to sting her on the right arm. The success of the treatment was surprising and complete. On the following night she was able to sleep, and the acute pain had all but completely disappeared; the arm was naturally a good deal swollen, owing to the stings, but the swelling quickly disappeared with cold-water dressing. The use of the arm gradually returned, and since there have been no symptoms of rheumatism. It is reported that the same remedy has been equally successful in several other cases. The cure no doubt was caused by counter irritation, and the treatment is analogous in its action to blistering, and the like. Moral: Let all rheumatic persons keep Cyprian bees.

WHY NOT USE THE NATURAL GAS IN OUR FACTORY?

I have been thinking of the wonderful benefit the people of this county are receiving from gas. It has made me think of you in your business. Just listen to me (though time may be precious). Think of a gas-well, with the pipes turned into your furnaces, running your machinery; then with smaller pipes running through all your rooms and into the stoves, then down to the —— where the "queen" lives, to warm up and light up the whole house, besides enough left for neighbors, etc.! Such a well we have in our county, also an abundance of oil. There are now 13 wells dug, all producing gas. One well throws, on an average, 100 barrels of oil a day; another throws 24 bbls. The 13th and last well is an enormous one, said to be strong enough to heat all Cleveland. The gas is found at about 1200 ft. in depth. The last well is now burning from a pipe stand of 57 ft., throwing a flame of from 50 to 70 ft. I suppose you have seen many accounts of it; don't you believe you, too, can find it in Medina by going down after it? Have you thought of it? It's worth thinking about. Or send Ernest here to start up a shop. Many manufacturers are looking this way. Just come and see for yourself. Before the last well was under control I took a broom-handle and tried to hold it over the six-inch escape-pipe (now remember I mean the broom-*handle*), and it would take it to this side and that with a "Zip, hiss, sizz," etc. You can imagine a little its great capacity. I am looking forward to the time I can control my cellar for the bees to a dead certainty. Over 4000 stoves in Findlay are being heated by gas this winter. The charges are $12.00 a year for one stove; but the probability is, that it will be one-half less next winter. That is as cheap as wood, and you don't have to carry out ashes, and there is no muss. As I look out to the east, I now can see the great light 12 miles away. I should have said, perhaps, that while the gas escapes it makes a wonderful roaring—so much so, that a train of cars can't be heard when equally distant. S. H. BOLTON.

Benton Ridge, Hancock Co., O., Feb. 11, 1886.

Thanks for your suggestion, but Ernest has his hands full at the Home of the Honey-Bees. About the time father started in bee-keeping he had the natural-gas hobby too. He accordingly sunk a well, but he didn't even "strike ile." Very recently one of our townsmen sunk a well to the depth of about 1200 ft., at a cost of as many dollars, but the attempt resulted in an entire failure as far as obtaining gas was concerned, or any thing else, for that matter. ERNEST.

TYPE-WRITERS—WHAT ONE TO BUY.

Referring to page 54, GLEANINGS, let me say, do not be fooled by the *pretty writing* of the Hall type-writer. The cost is $40.00. I have used one—*neat work*, but *hard slow work*. I was in love with my Remington, but was induced to try the *improved* caligraph, and I will say that the improved caligraph has about *twenty good points* over the best Remington. The same man invented both, and controls his patents. Several of the departments in Washington are *now* using caligraphs.

D. H. KELTON, Captain 10th Infantry.

Cantonment on Uncompahgre, Col., Jan. 28, 1886.

We are very glad indeed to get your opinion in this matter, Captain K., for we have known you for a good many years, and feel sure that your opinion is unbiased, and that you seek only the best good of bee-friends. Very likely the Hall type-writer might do good service where there was not a very large amount of business.

IS REVERSING OF FRAMES NECESSARY?

Some have said to me that they did not favor giving new swarms much brood. Why not? This is just what they make for themselves as soon as they can; and if left to themselves it will be three weeks before their number will be reinforced by young bees, during which time the force of working-bees is continually growing less. If it is desired to completely fill the brood-chamber with brood, as per the reversible-frame plan, alternate the frames of brood with fdn., when the combs are given to the new colony. If not so desired, place the brood in a body in the center of the hive, with fdn. at sides of hive. This latter plan, I am inclined to think, will prove more satisfactory in the end. This is on the ground that a shallow hive be used. I have one with 10 frames, regular L. size, but not so deep. I much prefer them to deeper frames, having cut down a lot of L. frames, and I would not change back again. I much prefer this method to the Heddon system for the prevention of after-swarms. And just now let me ask those who intend to use the Heddon system another season, to try this plan with a few colonies, and see for themselves if it hasn't decided advantages. It also affords a good opportunity for those who wish to raise any number of "swarming-impulse" queens, which may be taken from the colony on the old stand. This method, or a similar one, was suggested by W. B. House about three years ago, in GLEANINGS, since which time I have heard nothing of it. I have given it several years' trial, and am well enough pleased with it to continue, and without the use of reversible frames. Now let us see if reversible frames are not generally discarded by those who now are foremost in advocating them. C. W. KING.

Kibbies, Mich., Feb. 10, 1886.

MOTH WORMS THE CAUSE OF BAREHEADED BEES.

I want to corroborate the *thought* of C. C. Miller, in GLEANINGS for Jan. 15, in regard to "bare-headed" bees. I *know*, and am satisfied that it is caused by wax-worms. Several years ago I was worried by occasionally finding a comb with more or less bees uncapped, and was disposed to blame the queen; but accidentally I found a worm in the line of uncapped bees. Further investigation proved this to be the cause. I invariably found the worm. They invariably run in rows or circles, and the dead bees are generally fastened to the bottom of the cell by a web. I had to accept this theory as the cause. This last summer, noticing a row of uncapped bees in one of my combs, I said to myself, "Here is a worm;" and on digging out the row with my penknife, out comes the expected worm. This was the more noticeable to me from the fact that I had not seen a moth or worm since I came to this State, three years ago, and had come to the conclusion that bees were not bothered with them here; and in fact this is the only one I have seen. I have no doubt but you will find the worm, nine cases out of ten, upon investigation. M. H. SNYDER.

Arkansas City, Kan., Jan. 23, 1886.

Friend S., I am quite familiar with uncapped brood caused by moth worms, and I find it exactly as you describe. The bareheaded bees I have described in the A B C book are quite a different matter indeed. The patch is not oblong, but a complete cluster of cells. The capping is not torn, as where moth worms have been at work, but the cells are carefully fixed up in regular order around the heads of these uncovered bees. See reports elsewhere.

"WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT," HAS GONE DEEP AND TAKEN ROOT; REVERSIBLE FRAMES.

I was very much amused when I read the article of Dec. 15, "What to Do," etc. On page 861 it says, "Get some experienced farmer to tell you how much it would be safe to offer for old manure piles." Why, bless you, if you were out here you could get a train load for hauling it away. Your articles have gone down deep, and have taken root at Sunny Eden, a little farm of four acres. We do not think the cobble-stone drains would work in this locality. Do you think a sandy clay will hold water? The subsoil is two feet deep here. I expect to give your advice a practical test.

As we have not used reversible frames, we are in a dilemma as to whether they are an improvement or not. We should like to have this decided, as we wish to use only the best hive and frames. We do not want to make too rash a blunder by changing from this hive to that, just because some one advises it who has had long years of experience, but has not made a test of more than six months, or perhaps not that long, of the plan. W. S. DORMAN.

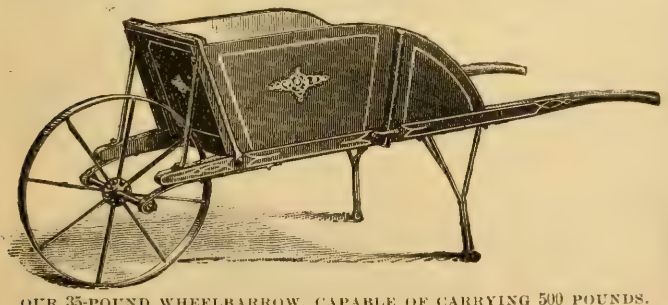
Mechanicsville, Iowa, Jan. 28, 1885.

Friend D., if you are where you can get good manure for drawing it away, and the distance is not great, you certainly ought to build up an immense business in market gardening. The cobble-stone drain, as you term it, will work in any soil where there is ever a surplus of water. Of course, the water will not stand as long in sandy or gravelly soil as it does in clay, but it would usually stand long enough to be a benefit to the growing crop.

ANOTHER WHEELBARROW FOR BEE-KEEPERS.

A WHEELBARROW FOR WOMEN, CHILDREN, AND PEOPLE WHO ARE NOT VERY STOUT.

WHEN I got our gas-pipe wheelbarrow I had been greatly disgusted by our wheelbarrows breaking down, rotting to pieces, and giving out when I didn't want them to. Well, the iron wheelbarrow remedies these defects. They will get rusty, it is true; but they never rot and never break, or rarely. On one occasion one fell from the top of our factory, loaded with brick, because of a rope breaking; but it was a pretty good wheelbarrow, even after it got to the bottom. There is only one trouble with it. Being all metal, it is necessarily pretty heavy. Sometimes when I go down across the creek for a wheelbarrow load of green corn, I conclude the wheelbarrow is heavy enough for me, without any load on it. Well, I have several times felt as if I should like to try my hand at making a wheelbarrow of our strongest wood and our best steel, properly braced and arranged so as to give strength, and yet not weigh one ounce more than is absolutely necessary. At the Ohio State Fair last year I found a wheelbarrow that came so near filling the bill that I asked the manufacturers how cheaply they could make 100. The wheelbarrow was all I could desire; but the price, I thought then, was more than we could stand. During the winter, however, they made a proposition which I considered very reasonable, providing they could make them at their convenience, when times were dull. Well, friends, the wheelbarrows are here, and they are a surprise to everybody. We show you a picture above.



OUR 35-POUND WHEELBARROW, CAPABLE OF CARRYING 500 POUNDS.

We have two sizes — the larger one weighing only 35 lbs., and yet it will carry 500 lbs. safely, and it can be packed so closely together for shipment that you can take the whole thing under your arm and walk off easily. The wheel has flat spokes instead of round. The different pieces are all cut and forged by means of dies. The legs are steel, so they will neither break nor bend, even if you bump them on the sidewalk. The springs are oil-tempered, with adjustable bearings, so you can tighten them up for wear. More than all, the wheelbarrows are the nicest job of painting and varnishing, I believe, I ever saw, for a farm implement. They are handsome enough to go around town with, and strong enough to do heavy work; and yet the price of the small size is only $4.00, the same as our iron wheelbarrow. The larger size is $4.50. The only discount that can be made is 5 per cent off for two; 10 per cent off for five, or 15 per cent off for ten or more. They can be sent either by freight or express. It is only five minutes' work to put one together.

NOTICES OF PRICE LISTS RECEIVED.

A. H. Duff, Creighton, O., sends an 8-page list of bees and poultry.

B. D. Sidwell, Flushing, O., sends a price list of Plymouth Rock poultry.

F. J. Crowley, Batavia, N. Y., sends us his 12-page price list of bee-supplies.

W. S. Cauthen, Pleasant Hill, S. C., sends his 8-page list of bees and queens.

G. W. McKallip, Hiawatha, Kan., sends a 12-page circular of apiarian supplies.

E. S. Brooks, Silverton, Oregon, sends a 13-page price list of supplies in general.

Henry Cripe, of North Manchester, Ind., sends his 3d annual 40-page list of supplies in general.

F. A. Snell, Milledgeville, Ill., sends us a 15-page descriptive catalogue; specialty, the Eclipse bee-hive.

E. M. Hayhurst, of Kansas City, Mo., sends us his postal-card circular—a printed list of bees and queens as a specialty.

T. G. Newman & Son, of Chicago, send their 35-page price list of apiarian supplies. Among the noticeable features of their list for '85, we notice the Heddon hive figured and illustrated.

Mrs. Lizzie E. Cotton, West Gorham, Me., sends out her annual circular of 32 pages. It is written in her usual bitter and censorious style, and breathes "threatening and slaughter" to the bee-journals and supply-dealers in general, which alone is enough to indicate that trouble may be expected by all who deal with her. We can only add our old stereotyped paragraph, which we always refer to when asked in regard to her standing. It reads thus, and probably always will:

> I am being asked my opinion of the new circulars Mrs. Cotton is again sending out quite plentifully. The statements she makes, and the prices she charges for the goods she sends out, would, in my opinion, forbid her being classed with our regular supply-dealers, to say nothing of the strings of complaints against her that have filled our bee-journals for years past.

John A. Thornton, Lima, Ill., sends a sheet concerning bee-supplies and Plymouth Rock poultry.

F. A. Salisbury, of Geddes, N. Y., sends a 30-page price list of apiarian supplies; also containing much valuable information besides.

Chas. F. Muth & Son, of Cincinnati, send a 30-page catalogue of apiarian supplies, besides a good deal of useful information. Among the notable features, we notice their new all-metal smokers listed.

Among the circulars recently printed at this office we notice the following

R. Schmidt, Caroline, Wis., a sheet, of apiarian supplies in general.

L. J. Trip, Kalamazoo, Mich., a 4 page price list of Italian bees and queens.

Oscar F. Bledsoe, Grenada, Miss., a 5 page price list: Italian queens a specialty.

Geo. W. Baker, Milton, Ind., an advertising sheet of bees, queens, and bronze turkeys.

Oliver Foster, Mt. Vernon, Iowa, an 8-page circular of queens, and bees by the pound.

A 14 page catalogue for J. M. Jenkins (mentioned on page 75). Specialties, bee-hives and implements. This catalogue contains a large amount of instructive matter, besides the prices it gives.

Hutchinson & Taylor, Rogersville, Mich., a 4-page price list of bees, queens, hives, sections, etc. As Mr. Hutchinson has adopted the new Heddon hive, he will now offer his old ones for sale.

TOBACCO COLUMN.

THE SMOKER AS A MEMENTO.

WHILE I was perusing the letters in the Tobacco Column, I was at once reminded of the fact that, three years ago last August, I, too, upon the impulse of the moment, quit the use of tobacco (for I had become an inveterate user of the vile weed, both chewing and smoking), and I also have a vivid recollection of informing you of the fact of my quitting the use of tobacco, and soon after I received a smoker from you, which I preserve with the utmost care as a memento from one who is doing in a manly and praiseworthy way what he can to reclaim his fellow-man from a habit which is not only nauseating, but perfectly useless and disgusting. I, too, have plead with many, and have so far persuaded some to quit the awful habit, that they would throw their old pipe and what tobacco they had into the stove, or elsewhere, and declare they would use the vile weed no more. How many have kept good their promise, I can not say. But for one I can say that, since I resolved to quit it, I have never touched, tasted, nor handled it, and with the help of God I never will again. F. W. THOMPSON.

Quincy, Ill., Oct. 20, 1885.

HAS USED TOBACCO 20 YEARS, AND ONLY 26 YEARS OLD.

After using tobacco twenty years I have quit, and never expect to use it again, although I am only 26 years old. If you think I deserve a smoker, please send me one; and if I take up the habit again I will pay for the same. G. B. ALLEN.

Rocky Hill Sta., Edmonson Co., Ky.

A "THOUSAND TIMES OBLIGED" FOR SO NICE A SMOKER.

I am a thousand times obliged to you for the smoker you sent me. It is more than I expected. Really, I did not look for a smoker at all. I did not know but it was like all the humbugs we read about. There are not many men who would give away an article that costs as much as that did, for the small sum of nothing. L. F. COUSINS.

Utica, Pa.

COMMENCED THE USE OF TOBACCO, BUT PAYS UP LIKE A MAN.

Inclosed you will find the cash for the smoker and tobacco contract which is due you. You sent me the smoker in good faith, and I commenced the use of tobacco again. I will pay up like a man.

Centreville, Ind., Jan. 1, 1886. B. C. NEFF.

GONE BACK TO TOBACCO, BUT PAYS FOR THE SMOKER.

As I have commenced the use of tobacco again, please find inclosed one dollar to pay for smoker you sent. I quit long enough to save more than the price of a smoker.

Here is my report for last season: 26 swarms in the spring; increased to 50 good swarms, got 198 lbs. of comb honey, and 1170 lbs. extracted, or an average of $52\frac{2}{3}$ lbs., spring count. EDWIN HUBBARD.

Oil City, Monroe Co., Wis.

A HARD STRUGGLE.

I have given up the use of tobacco. It was a hard struggle, but I have gained the victory. I think I am not as nervous as I was; and by the help of God, I hope I may never use it again. It is awful when a man puts himself down to be such a slave to such a filthy weed. C. M. HICKS.

Fairview, Md., Nov. 10, 1885.

KIND WORDS FROM OUR CUSTOMERS.

GLEANINGS is a welcome visitor. I would not do without it for thrice its cost. E. E. BENDER.

Aspen, Adams Co., Pa., Feb. 8, 1886.

YET TO FIND FAULT.

I have yet the first time to find fault with a single article I have purchased from you. All proved perfectly satisfactory. FRANK MURRILL.

Bonsacks, Va., Dec. 26, 1885.

THE A B C CHEAP AT DOUBLE THE PRICE.

The A B C book came safely to hand yesterday, and I must say that I was surprised to see so large a volume for only $1.25. I consider it cheap at $2.50.

Pharisburg, Va. T. T. PHLEGAR.

GLEANINGS FULL OF NEW IDEAS.

I have taken GLEANINGS for the past two years. My time expired Dec. 15. I did think I would drop it for this year; but as there are so many new inventions and ideas coming up, I guess it will be for my interest to have it continued.

Fair Haven, Rutland Co., Vt. E. L. WESTCOTT.

OUR MODE OF PACKING.

The trunk and contents arrived to-day, with every thing safe and sound. I much admire the neat and safe packing of the goods. I think you must have an experienced hand at the packing business, as I never have had goods packed so neatly and securely. Accept thanks for your promptness.

Bowman, Ga., Feb. 1, 1886. J. D. BROWN.

THE QUEEN A LIVELY ONE.

The queen you sent last June came all right. She was a lively little thing; for when I let her loose on the comb she ran clear to the bottom of the hive before she slacked her motion. She changed the whole colony in about two months, from blacks to yellow-banded workers. Thank you for your promptness. A. J. SHEPARD.

Walker, Linn Co., Iowa, Jan. 22, 1886.

A FEW MORE OF OUR 20-CENT SHEARS.

I want a few more pair of those 20-cent shears, to finish supplying my neighbors. I have already had eight pair. Nearly every one who sees them wants a pair. I have made out an order for the shears and a few other articles from your counter. ADELBERT COOK.

Norwich, Chenango Co., N. Y., Feb. 8, 1886.

THE PARKER FOUNDATION-FASTENER.

I read the essay you gave at the Detroit convention, with much interest and entire approval, but could hardly see how you overlooked a cheap foundation-fastener. Last year I bought of James Heddon a Parker foundation-fastener at 25 cts., which I understood came from your shop, and I could better afford to buy one every week during the busy season than to do without one. O. B. BARROWS.

Marshalltown, Ia.

SOME KIND WORDS FROM ONE WHO IS NOT A BEE-KEEPER.

I am a stranger to you; but Mr. Woolley is a member of our family, and takes GLEANINGS. I read Our Homes and Myself and My Neighbors, and write to thank you for them. We live in the big woods, and have very little preaching, so it is doubly welcome. I am an English woman, and send kind regards to you and wife and family. Please accept best wishes, both temporal and spiritual. MRS. S. A. SHALE.

Kingston, Minnesota, Dec. 4, 1885.

[May God bless you, my good friend, for your kind and encouraging words. My dear wife is one of old England's daughters, and I am sure she will be glad to know that my efforts have been helpful to those who are deprived of the regular preaching of the gospel. May the Lord be with you and all your friends in your far-away home.]

THE STORY OF THE BIBLE.

Will you please send to my address a copy of "The Story of the Bible"? I sent for one a year ago, and my little niece has taken such a fancy to it that I wish to make her a present of one.
EMILY JENKINS.
Milan, Ill., Dec. 14, 1885.

OUR JOB WORK GOOD.

The circulars received—an exceedingly neat, a *perfect* job. Let me thank you, especially for the reduction in price, the printed matter being less than you at first thought there would be, and at first quoted for. You could have made the additional $4,00 out of me without my ever knowing any better. If you act in that way as a rule, you are certainly an honest man.
OSCAR F. BLEDSOE.
Grenada, Miss., Feb. 15, 1886.

WHAT THE EDITOR OF THE POULTRY AND FARM JOURNAL THINKS OF GLEANINGS.

Your Jan. GLEANINGS is at hand. I gladly put you on the exchange list, and forward Jan. *Journal* to-day. I am greatly pleased with Ira D. Granger's words on 31st page; and with a journal whose impress is out-and-out for Christ, everywhere. Please accept my earnest congratulations to an editor who *mixes* religion into all his business. It is a good *leaven* to use.
T. T. BACHELLER.
Minneapolis, Minn., Jan. 29, 1886.

IT PAYS TO ADVERTISE IN GLEANINGS.

I find it pays to advertise in your *fresh* and *vigorous* GLEANINGS. My other "ad" in GLEANINGS cost me the trifle of sixty cents, and yet it brought me more clean profit than the best-paying postoffice in our town brings per year. It is a law of reason, that *the man who won't advertise his goods deserves to fail*. I had almost forgotten to say that the issue containing my "ad" was hardly out of the press before I began to have proposals. I believe your patrons are all live men, all in the front rank too.
G. A. FARRAND.
Rockport, O., Feb. 6, 1886.

A KIND WORD FROM FRIEND VIALLON, AND SOMETHING BESIDES.

I will ship one of my four-frame nuclei, between the 5th and 15th of April, 1886, to the bee-keeper who will have sent you the largest number of subscribers from January, 1886, to the first of April, 1886. Whoever he may be, he will not be sorry of the extra trouble taken to solicit subscribers for GLEANINGS.
P. L. VIALLON.
Bayou Goula, La., Feb. 9, 1886.

[Many thanks to you, friend V. Now, will those who apply for this premium name it when they send in clubs? Or if you have sent in any clubs already since Jan. 1, call our attention to the fact, that we may verify and put you on the list.]

GO ON IN THE GOOD WORK.

I inclose you one dollar for my next year's subscription. Go on in your good work, and God will bless you. You and I differ in some things; but you are honest, and honest men go to heaven. The one who has had the most advantages will have the most to answer for. If I have health and opportunity I will come to see you next year. I think a good talk with you would do me good. I have had many troubles and much tribulation, but have been blessed with a hopeful and courageous spirit, and a mind too active for a weak frame. I should esteem a man like you as a friend and neighbor, as a priceless boon. Pardon me for this.
GEO. E. HILES.
Hondo City, Texas, Dec. 3, 1885.

GLEANINGS A "CASKET OF SUCH GOOD THINGS."

The wrapper on my last copy of GLEANINGS informs me that my time expires with present number; and as I can not afford to lose a single issue, I haste to inclose one dollar for another year's subscription. I must say, that GLEANINGS is a most welcome visitor that never fails to come twice a month, with a casket of such good things that it is who will and who shall, among my wife, daughter, son, or myself, be the first to peruse its pages. May God bless and spare its noble-hearted editor for many long years to come, to send it forth as bread cast upon the waters, that may be gathered many days hence.
J. D. BROWN.
Bowman, Elbert Co., Ga., Dec. 25, 1885.

THE TIN TUNNEL FOR PUTTING UP BEES.

The goods I ordered of you were all received yesterday—nothing missing. You ought to see me in May, shaking bees through that tin tunnel, into cages to ship. I would not take $1.50 for my Morton's gold pen. I don't see how you can sell them so cheap. The gloves are large enough this time. I am all right for snow, or bees either.
W. A. SANDERS.
Oak Bower, Hart Co., Ga., Feb. 11, 1886.

OUR 35-CENT WHOPPER KNIFE.

I am proud to inform you that, after dealing with you for several years, more or less, I can heartily congratulate you on your honesty, integrity, and promptitude as a dealer in mercantile goods, and as a Christian gentleman. The last goods I ordered of you came to hand, giving the usual satisfaction. I make special mention of your knife, known as the "Whopper." It is just the knife for service, large and strong, well united, cheap; and as to metal, it is not to be surpassed by any knife. Since the first one came to us, several have been ordered; and all who get them are well pleased. Your steel shears have given the same satisfaction to all who got them. In fact, your way of dealing meets the expectation of all honest people.
NAT. T. DRAUGHON.
Clarksville, Texas, Dec. 10, 1885.

GOODS RECEIVED IN GOOD SHAPE.

The goods arrived in good shape, and give full satisfaction. Thanks. The A B C book is excellent, and I would not be without GLEANINGS, even if its price were $3.00 per annum. Last spring I caught the bee-fever, and it has been increasing ever since. I bought one colony of Italian bees. That single colony has given 210 lbs. of extracted honey, and has 4 daughters by artificial swarming. I tried to run the first swarm for comb honey, but had no success; they would not work in the sections, so I sent to you for an extractor. I got it, and it worked to a charm. I have adopted the improved Langstroth Simplicity hive. It is cheap, well made, and in regard to convenience it stands ahead of all sorts of hives I have seen. I winter my five colonies on their stands in good packing-cases, protected on the north and west sides by an eight foot-high board fence. They are all right so far.
T. H. DAHL.
Stoughton, Wis., Jan. 5, 1886.

A KIND WORD FOR THE WAY IN WHICH WE BIND BACK NUMBERS OF GLEANINGS.

I have just received the bound volume of GLEANINGS for 1885, in exchange for my old ones; and to say I am satisfied with the exchange hardly expresses it. I have been binding them myself heretofore, but will do so no more as long as I can get new ones so nicely bound for so low a price. I don't see how you can afford it; but if you can stand it, I think we ought to. Of course, every bee-keeper who is well posted, or wants to be, keeps his back numbers. There is great comfort and convenience in having them neatly bound; and when you can get a nice new volume for less than it ordinarily costs to get the old ones bound, every bee-keeper ought to have one of them. Where they can be sent by freight with other goods, the expense is insignificant.
J. A. GREEN.
Dayton, Ill., Feb. 9, 1886.

HOW $1.00 INVESTED IN GLEANINGS SAVED $5.00.

The editor's notice runs thus: "If I am correct, your subscription expires with the present number," and then the question arises, "Have you found GLEANINGS a good investment?" Now, kind reader, I commenced bee-keeping in 1885 with three swarms, purchased the fall previous, and increased to eleven by natural swarming. My first swarm was two at once, and clustered in one place. With the assistance of GLEANINGS I caught one queen before the bees balled her, and then divided the bees and put them into separate hives, and they went to work, blacks and Italians, in both hives, all mixed up, and to-day I have them in the cellar, doing well. I think I saved five dollars, so I am under the impression that I did not make a bad investment. Some people count every thing by dollars and cents; but GLEANINGS has some things in it that I can not count on in that style, for which I highly prize it and subscribe for it once more.
G. STRANGWAYS.
Elora, Ont., Can.

GLEANINGS IN BEE CULTURE.

Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER,
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, MAR. 1, 1886.

Fear not, little flock; for it is your Father's good pleasure to give you the kingdom. LUKE 12:32.

BARNES' LATEST IMPROVED POWER BUZZ-SAW.

WILL those who have purchased these machines, please tell us how they work? If possible, how they work compared with the old style?

GREGORY'S LITTLE BOOK ON FERTILIZERS.

AFTER a hasty review of the sample copy sent us, we think the work is one that will prove of very much value to every one engaged in raising plants. See advertisement in this issue.

DISCOUNTS FOR THE MONTH OF MARCH.

THESE are the same as those given for February; namely, 10 per cent off on foundation, and 5 per cent off on sections; but only 2 per cent, instead of 3, additional, on orders received during the month.

MATTER FOR GLEANINGS.

AGAIN we find it impossible to find room for great numbers of good articles. Under such circumstances, we are compelled to use the best of our judgment in deciding what shall or shall not fill the pages.

SENDING US BEE-HIVES TO EXAMINE.

DON'T send me any more bee-hives without first writing me about them. We have not room to store them until we can write you, and I have not time to look them over, to pass an opinion on them. Besides, I do not believe we want any more hives than we have already. There are too many now. If you have something that is away ahead of any thing heretofore discovered, give me a rude sketch of it on a piece of paper. After looking at this, if I want to see the hive I will tell you.

ANOTHER BEE-JOURNAL.

A VERY pretty-looking journal on bees and poultry, called *Rays of Light*, is at hand. The name, certainly, is different enough from any other now in the field to prevent confusion on that score, and I don't suppose we shall ever have too many "rays of light" while the world stands. We have been a little backward lately about mentioning new journals, because so many start up, run a little while, and stop without even so much as making good their unexpired subscriptions. I have been wondering if it wouldn't be a good plan for new bee-journals to give some reference in regard to their standing, and financial ability to keep the thing going for a whole year at least. *Rays of Light* comes from J. J. Martin & Co., North Manchester, Ind., who is quoted by Bradstreet as having means and ability to publish at least a 50-cent magazine.

MUTH'S COLD-BLAST SMOKERS.

OUR old friend Muth has started something new in the way of a smoker having a bellows made of tin, so the smoker is all tin except the leather. This all-metal cold-blast smoker is much like ours in appearance, except the material of which the bellows is made. Price 50 cts., or five for $2.00. By mail, 25 cts. extra. An improvement on this, which he calls the "Perfection," has a valve in the bent air-tube, to prevent the smoke from being drawn back into the bellows. Price of the Perfection, 75 cts.; five for $3.00; either of the above, 25 cts. extra when sent by mail. The third is a muzzle feeder, something on the style of Bingham's. The fire-pot, also, has an extra covering of tin, to prevent burning the fingers. Price of muzzle feeder, $1.25, or five for $5.00. By mail, 35 cts. each extra. We can furnish them at the above figures.

NICE HONEY FOR ONLY 7 CTS. PER LB.

ONE of the bee-friends has just sent us a beautiful lot of honey in sap-pails, and he wants the pails right back for sugar-making. A good part of the honey is clover, but is flavored more or less with basswood, and it is *beautiful thick honey*. To close it out at once, he offered it at such a low price that I can send you a 58-lb. iron-jacket can full at only 7½ cts. per lb., or an even $4.25 for the whole package (the iron-jacket can being worth 58 cts.). If you will take two cans full, you may have it for only 7 cts. per lb., or an even $8.00 for the whole 116 lbs., *cans included*. Of course, this offer is for immediate orders. Sample free on application.

P. S.—We have just secured two barrels of raspberry honey, which we will sell at the same price as the above; or if you will take a whole barrel of 46 gallons, we will make it 6½ cts. No charge for the barrel. Sample of the latter, also, free on application.

A CRATE TO HOLD SECTIONS ESPECIALLY FOR THE CHAFF HIVE.

WE are now making a crate of this description on the J. E. Moore plan. It holds 32 regular Simplicity sections, or 36 7-to-the-foot sections. Of course, this style of crate does not admit of the use of separators. The price of the crates, made up, is 20 cts. Two of them fill the upper story of a chaff hive nicely, taking 64 ordinary sections, or 72 7-to-the-foot sections. Now, although this arrangement takes nearly the same number of sections as the wide frames, the expense of the arrangement is considerably less. As to whether we would advise this in preference to the arrangement of wide frames, we can not answer. The J. E. Moore case has been received with considerable favor, and doubtless many will prefer the arrangement. One good thing in their favor is, that you can get at the lower story so much easier, having only two cases to remove instead of ten wide frames. We can furnish the above in the flat at the same price as the regular S. size; viz., 1, 16c; 10, $1.35; 100, $12.00.

BASSWOOD-TREES, DIFFERENT SPECIES.

IN Ellwanger & Barry's illustrated catalogue of ornamental trees for 1886, you will find mentioned 14 different varieties of basswood, or linden. I was at first tempted to order a tree of each kind, to test them for honey; but a good many of them cost a dollar apiece, so it would be a somewhat expensive experiment. The distinguishing features, as I understand it, are the shape and size of the leaf, and the color of the buds and young branches. In planting our basswood orchard, some twelve years ago, I noticed we found little trees in the forest, some of which were red and others yellow; so it seems to be an accidental and common feature; and if the trees are in no way different, except the color of the bark, which is quite probable, it will not be worth our while to make the experiment. The white-leaved weeping linden, or the cut and fern lindens, are ornamental trees for the lawn or dooryard. The same catalogue gives two different kinds of tulip, or whitewood trees; namely, the common and variegated leaved. Now is the time to order basswoods, if you are intending to put them out this spring. See prices in our new price list.

REDUCTION IN THE PRICE OF SAP-PAILS.

As the sugar-making season is approaching, sap pails and spiles will be needed soon. We are pleased to tell you that the price of these has declined. We can furnish sap-pails, made of IC charcoal tin, 10 qt., for $14.00 per 100; 12 qt., $15.00. IX charcoal, 10 qt., $16.00; 12 qt., $17.50 per 100. Sap-spiles, best retinned, at 10 cts. per doz.; 75 cts. per 100, or $7.00 per 1000. The spiles can be sent by mail for 6 cts. per doz., or 45 cts. per 100, extra. Wooden sap-pails. $12.00 per 100. These are put up in packages of one dozen each; and in every dozen there are two pails with bails. The rest have no bails.

Three-eighths-inch bits for tapping trees, 15 cents each; postage, 3 cts. extra. Brace for same, with set-screw, 20 cts.; 18 cts. extra for postage, if sent by mail. Brace with patent grip, 50 and 75 cts., according to size. Gallon syrup-cans, guaranteed not to leak, $1.20 for 10, or $11.00 per 100. Oblong tin pans, for making maple-sugar bricks, $2.75 per 100.

Please note that the law now requires that the name of the person who puts up maple syrup must be put on the package in letters not less than one inch high, and three-eighths of an inch wide. We are prepared to print labels in accordance with the above law; and where desired we can paste them on your cans, so you have nothing to do but to fill them with syrup.

REDUCTION IN THE PRICE OF BEE-SUPPLIES, ETC.

MARCH 1, 1886, your humple servant, A. I. Root, is enjoying himself with the "New Agriculture." You see, we take the exhaust steam, after it has warmed our buildings, and put it down through those stone reservoirs I told you about on page 58, and it has made the ground warm enough so we are setting out all kinds of hardy plants, and making them grow as in June. When there comes a zero freeze, we have to put a sash over them. Sash is a great deal better than any kind of cloth covering, especially for a hard freeze. Ernest and John, with the help of a great lot of other of *your* friends, are taking care of the journal and the price list. Perhaps that accounts for the large department of Kind Words that appears in this number. They thought they were all right, and so I let them go. And, by the way, Ernest and John and these other friends have been figuring on the cost of a great many of these things we make for you, and have declared so positively that the goods can be sold cheaper, that I have consented to a big reduction in the price of many things in our price list. The reduction is so great, in fact, that we have decided to mail a new price list to every one of our subscribers. This will be done just as soon as this journal goes to press. In fact, we have got it out a little ahead of time with that very end in view.

We have received, during the month of February, 401 new subscribers; but during this time 358 have expired and have not renewed, so we are only 43 ahead, making 5024.

A NEW EDITION OF THE A B C BOOK.

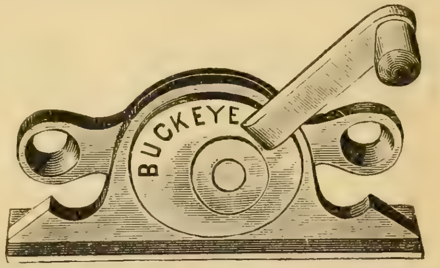
THIS is now out of the press, making the 27th thousand. It contains mention of almost every thing of importance up to the present date, even including a notice of Heddon's new hive, as well as cuts and descriptions of his hive of a year ago. As we said before, if you already have an A B C book, and sell it to somebody for half price, we well sell you a new one for the money you get; that is, the new edition will be half price to those who have recently purchased the edition before it.

BUCKEYE SASH-LOCK

A Device to Fasten Windows up or Down, Or at Any Point.

Something Effective, although Low in Price.

For many years I have been trying to get something better to hold a window up than a stick or a book, or something of that sort; but although we have tried them, even paying as high as 75 cents per window, I have never had any thing please me so well as the little device illustrated below.



This device holds the sash securely by friction in any desired position, as tight as if it were in a vise. It prevents the sash from rattling, and excludes the dust by making tight joints, and yet it does not mar the wood. It is put on with two screws, and can be fitted by an inexperienced hand in three minutes. It works equally well in upper or lower sash, with or without weights. Printed instructions are furnished with each one, as well as screws to fasten them on with, and yet the price is only 5 cts.; 10 for 48 cts.; 100 for $4.00. If wanted by mail, add 3 cts. each extra. The little device is the invention of one of our Medina Co. boys.

A. I. ROOT, Medina, O.

15 PLYMOUTH-ROCK EGGS by express for $1.00.

CHAS. DADANT & SON,
3btfd **Hamilton, Hancock Co., Illinois.**

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was $40.00, but we will now sell it at half price, or $20.00.

Also one exactly like it, owned by W. W. Bliss, of Duarte, Los Angeles Co., Cal. There is nothing wrong with these mills, except that the rolls are of smaller diameter than those we now make, in consequence of which they do not make quite so thin fdn. right in the middle of the rolls as those made now with rolls of a larger diameter. They will, however, roll narrow sheets equal to any, and will roll sheets a foot wide; but when of so great a width, the center is a trifle thicker, as explained above.

Also one 9-inch Dunham mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $20.00. The list price of a new mill of this kind is $40 00. **A. I. ROOT, Medina, O.**

C. W. PHELPS & Co., Tioga Centre, Tioga Co., N. Y.

WANTED.—To exchange Italian bees or queens for ferrets, Wyandotte pullets, or eggs for hatching; also one or two pair of fancy pigeons. Stock must be first-class. F. BOOMHOWER,
5d Gallupville, Schoharie Co., N. Y.

WANTED.—To exchange, telegraph instruments, keys, relays, and sounders, for bees.
5d E. F. WILCOX, La Grange, Lorain Co., O.

WANTED.—To exchange bees for a Barnes-saw, foundation-mill, or Light Brahma fowls; or I will sell bees by the pound; also queens in season.
JAMES P. STERRITT,
5-6-7-8d Sheakleyville, Mercer Co., Pa.

WANTED.—To exchange Simplicity hives for a circular-saw mandrel for hive-making by steam power. Will sell hives (in the flat) cheap for cash, or will take one-third pay in full colonies of bees. Hives in any quantity to suit customers, up to a carload per day. G. A. FARRAND,
3tfdb Rockport, Cuyahoga Co., O.

WANTED.—To exchange for a farm, or sell my place, consisting of 7½ acres of ground in the town of Lewisville, Ind. A small dwelling, poultry-houses, stable, and an everlasting gravel-bank, which affords about 3000 loads of gravel every year, which sells readily at from 10 to 15 cts. per load. The place is in a good honey locality, and good shipping facilities. Apiary slopes to the south and east; is surrounded on the north and west by a tight plank fence, about 7 ft. high. Apiary is set in grapevines. I will give five years' time, if sold. Direct all communications to
3-5-7d GEO. W. BAKER, Milton, Ind.

WANTED.—To exchange Brown Leghorn eggs for hatching, S. C., for foundation, also for sale; $1.00 for 13; 30 eggs for $2.00; 75 eggs, $4.00.
5d R. J. NASH, Williamson, Wayne Co., N. Y.

WANTED.—To exchange foundation for wax.
5tfdb B. CHASE, Earlville, Madison Co., N. Y.

WANTED.—To exchange large, good piano for bees; also pure-bred B. Leghorn and Partridge Cochin eggs, for bees by the pound.
5 6d L. HARRIS, Box 304, Greenville, Ill.

WANTED.—To exchange berry-plants for 1 dozen warranted Italian queens from the South. Will also take supplies. See our small-fruit and poultry circular, free. S. P. YODER,
5d E. Lewistown, Mah. Co., Ohio.

WANTED.—To exchange, Apiarian supplies for Italian bees. Circular free.
5d L. J. TRIPP, Kalamazoo, Mich.

WANTED.—To exchange Italian bees or queens, or comb fdn., made on the Given press, for a second-hand engine, 1 or 2 horse-power.
5d L. HEINE, Bellmore, Queens Co., N. Y.

WANTED.—To exchange, telegraph instruments, new, and silverhull buckwheat, for supplies, bees, or offers. C. D. MANVILLE,
5d La Grange, Ohio.

FOR SALE. Italian Bees, 10 Langstroth frames, $7.00 per colony; 2 for $13 00; 2 frame nucleus with queen, $12 00. JANE E HUNTINGTON,
5d MILLBORO DEPOT, BATH CO., VA.
(Formerly of Cotton Hill, W. Va.)

SUPPLIES VERY CHEAP!

ITALIAN BEES, BEE-HIVES,

SECTIONS, FOUNDATION, EXTRACTORS, SAW-MANDRELS, ETC.

As I manufacture all kinds of supplies, I can sell very cheap. **E. Y. PERKINS,**
5tfdb **Jefferson, Greene Co., Iowa.**

CLOSING OUT!

Desiring to move about Apr. 1, I shall sell and deliver at depot, before that time, 32 colonies of Italian and hybrid bees in 2-story Simplicity hives, 20 L. frames, at $5.00 each. Also one Novice Honey-Extractor, L. frame, and knife, for $5.00. One Barnes combined circular and scroll saw, with 2 saws, one emery wheel, counter-shaft for power, and all the necessary guages, for $25 00. Cost $50.00. As good as new. Orders must be in by March 20, or I will sell at auction. Safe arrival guaranteed.

5d **J. H. Reed, Orleans, Orange Co., Ind.**

PURE ÷ ITALIAN ÷ QUEENS

BRED FROM AN IMPORTED MOTHER,

Sent by mail; safe arrival guaranteed, from April until October, Tested Queens, $1.50; Untested Queens, $1.00; per dozen, $8.00. Satisfaction guaranteed, or money refunded. 5 7-911-13d
Walter McWilliams, Griffin, Ga.

LOOK ÷ HERE.

What you can get for $3.00. A 3-frame nucleus on L. frames, containing two frames of brood, Italian queen, frames covered with bees: 75 Italian queens will be sent to fill first orders. Such nuclei as I send will not only grow into strong colonies, but will doubly pay all expenses with surplus honey. A great many customers have reported over $8.00 from each nucleus. If you want full colonies, or bees in any form *except* by the pound, write me before ordering elsewhere. Orders will be filled from the 25th of May to June 15. 5tfdb

Send address on a postal to

W. ATLEE BURPEE & CO., PHILADELPHIA, PA.

PURE ✣ ITALIANS ✣ EXCLUSIVELY.

STOP, ✻ READ, ✻ AND ✻ ORDER.

Having determined to devote my time and attention exclusively to the production of pure Italian bees and queens, during the season of 1886, I offer, in order to reduce stock, **50 Choice Colonies of Pure Italians** in 10 Langstroth frames, guaranteed to contain at least 4 full frames of brood and 4 lbs. of bees in new chaff hive, at $10.00 each. I append my prices for the season.

My terms are cash with the order. First orders will be filled first. I will refund money at any time a customer may become dissatisfied with waiting.

My methods: One kind, and the best of that kind. Nothing except tested queens sold at any price. I will send one-year-old queens until stock is exhausted, and then this season's hatch. I will commence to send, about May 1st.

1 tested queen..................................	$1 00
1 pound of bees	1 00
1 frame of brood and bees..................................	1 00
1-frame nucleus, tested queen	$2 00
2 " " " "	3 00
3 " " " "	4 00
4 " " " "	5 00

In lots of 5, five per cent discount; in lots of 10, ten per cent discount. In lots of 10 or more nuclei or pounds of bees, I will pay express charges for the first 1000 miles. Now remember, I guarantee safe arrival and absolute satisfaction in all cases. Sample of live workers free by mail. Capacity, 25 queens per day after May 1st.

I append a few from hundreds of recommendations from last season's customers.

Sodus Point, N. Y.
I am very much pleased with the tested queen I got from you last summer. JAY S. SEELEY.

Port Dover, Ontario, Can.
I believe I can make arrangements with you for queens next spring, as what I have got from you please me very well. R. M. TAYLOR.
LATER.—*I will give you my trade for queens for 1886.* R. M. T.

Mill Point, N. Y.
Queen arrived in fine condition, and I am well pleased with both queen and bees. PETER KLINE.

Penetanquistan, Ontario, Canada.
Queen received all right, and alive. She is a noble-looking queen, and pleases me better than any I have yet received. H. T. LEACH.

HONEY AND BEESWAX.

Our market, and location as a trade center, the rapid growth of our city and country, gives us a large demand for honey. We have found it impossible to keep a stock of 1-lb. frames, unglassed, and of which we are in need. This style of comb sells much faster than any other and we will make liberal offers on receipt of samples. We are well stocked on 2-lb. sections, also extracted. Beeswax wanted on commission. **CLEMONS, CLOON & CO.,**

HONEY COLUMN.

CITY MARKETS.

CINCINNATI. — *Honey.* — No new feature in the market. Demand is good for jar goods in the jobbing way, and fair for choice comb honey, but very dull for barrel goods from manufacturers. Arrivals are plentiful. We quote extracted honey, 4@8c a lb. on arrival, and choice comb honey at 12@15c a lb. in the jobbing way. There is a good home demand for *beeswax*, which finds a ready sale at 25c a lb. on arrival.

CHAS. F. MUTH & SON,
S. E Cor. Freeman and Central Avenues,
Mar. 10, 1886. Cincinnati, Ohio.

ST. LOUIS.—*Honey.*—The market is dull.

White clover in 1-lb. sections,	14@16c.
Spanish needle, " "	11@12½c.
Prime,	9@10c.
Dark, and broken comb,	7@8c.
Extracted, choice, in cans	8@9c.
" good " "	7@7½c.
" in kegs	5@7c.
" bbls., as to quality,	4@6c.

Beeswax, in fair demand at 22½@23 for prime. Dark, 1@5c less as to quality.

Mar. 11, 1886. W. T. ANDERSON & CO.,
104 N. 3d Street, St. Louis, Mo.

CLEVELAND.—*Honey.*—The market continues very good for best 1-lb. sections of white at 14 cts.; second, 12@13; 2-lb. sections are dull at 12@13. Old, 9@10, and moving very slowly. Extracted, 7@8.

Beeswax, 25. A. C. KENDEL.
Mar. 10, 1886. 115 Ontario St., Cleveland, Ohio.

BOSTON. — *Honey.* — 1-lb. sections, 13 @ 14; 2 lbs., 11@12; Slow sale. Extracted honey, 6@8. *Beeswax*, 28.

BLAKE & RIPLEY,
Mar. 12, 1886. 57 Chatham St., Boston, Mass.

CHICAGO.—*Honey.*—Market is in good shape here at present, and all that is here will be closed out soon. Choice comb honey brings 16c in 1-lb. frames; extracted, dull, but really without much change in price. *Beeswax*, 25c. Comb honey wanted.

R. A. BURNETT,
Mar. 10, 1886. 161 S. Water St., Chicago, Ill.

DETROIT.—*Honey.*—The market continues dull; no market change from last quotations. White, in pound sections, 13@14c. Commission houses think they will be able to close out present stock before new honey comes in. *Beeswax* in good demand at 25@27c.

M. H. HUNT.
Mar. 11, 1886. Bell Branch, Mich.

MILWAUKEE.—*Honey.*—This market is good for choice comb and extracted honey at this time, and the supply is not equal to the demand. We can encourage shipments, and quote as follows:

Very choice clover, 1-lb. sections,	17@18
Choice " " "	16@17
" " 1½ " "	15@16
Old or dark, slow sale.	12@14
Extracted, choice, *pure*, in kegs or bbls.,	7½@9

Beeswax wanted, 20@25c per lb. A. V. BISHOP,
Mar. 10, 1886. 142 W. Water St., Milwaukee, Wis.

Vol. XIV. **MARCH 15, 1886.** **No. .6**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 5 or more, 75 cts. each. Single Number, 10 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

SECTIONAL BROOD-CHAMBERS.

Also Some Other Matters Pertaining Thereto.

SOME SUGGESTIONS AND DEDUCTIONS FROM DR. G. L. TINKER.

THE extensive discussions of the past year in the bee-journals on the modes and advantages of reversing brood-combs, as well as the result of trials, has proved that there is no profit in reversing combs singly, because of the labor required, not that there is no advantage to be gained from the practice. Like many other discussions in our journals, truth that we had sought—the germ of wheat sifted from all the chaff—is quite unlike what we had been seeking or had anticipated.

It is no new idea, by any means, that the getting of the brood close up to the sections in working for comb honey is a measure of great value. As the outcome of all the invention and discussion, we have discovered, perhaps, all of the plans by which the brood can be brought near the sections, so that we may now point out the one plan most practicable and valuable. And right here I wish to say that no one man is entitled to all the credit of the discoveries made, because all, or nearly all, bee-keepers have had a part in making them, and have prepared the fraternity for an innovation in our methods that, without this preparation of the apicultural mind, would have been impossible. The credit, I boldly assert, is due rather to the great fraternity of bee-keepers who have not only made discovery possible through their united labors, but now make the introduction of the new appliances and method certain. As one who has done most to favor invention and the evolution of new ideas on this subject, the editor of GLEANINGS should take a just pride in the work accomplished; but as the matter stands, one bee-keeper is as much entitled to the benefits of the work as another; and I trust and believe that all will look upon it in this light, and hesitate not by virtue of a just right to adopt the improved methods as soon as convenience will warrant, and the revolution in the construction of brood-chambers and in our methods of management will demand. But I am strongly convinced that nothing has yet been produced that will enable, to the fullest extent, the practical advantages that are to be derived from our new discoveries. It is my object, however, in writing this article, to throw some light on the subject.

But first, what is the most practical and advantageous method of disposing the brood near the sections at will? Beyond question, it is the proper management of the shallow sectional brood-chamber. Has it any disadvantages? We assert fearlessly that it has not, neither in wintering the laying of the queen, nor in the manipulation of hives or combs.

Until about five years ago, a hive, the brood-chamber of which was in three shallow sections, each $5\frac{1}{4}$ inches deep by 12 x 16 inside, has stood in this town, and contained bees uninterruptedly for 30 years. The colony, in its thin walls of walnut, had resisted the cold and the buffeting of the storms of 30 winters, and it at last succumbed to the depredation of robber-bees which gained entrance through its many rotten corners. It had always done well, was generally on hand with a rousing swarm in season, and, besides, made a liberal amount of surplus each year for its owner. When father Langstroth, a few years since, recommended a thin-walled hive for outdoor wintering I was quickly reminded of the old hive (the panels in the sides of the cases were not over ¼ inch thick). That it had not been manipulated on the modern plan of tiering up the cases and placing the brood next to the supers, was no fault of the hive. The combs were all attached to comb-bars in each case, on the Dzierzon plan.

REVERSING HIVES.

In a shallow sectional brood-chamber we think that there is no advantage whatever to be derived from reversing its sectional parts. The placing of the brood next to the super, and any honey that may be in the upper case below the brood, will accomplish all that can be done. We shall, therefore, have no use for a reversible hive. Again, as we shall not have occasion to handle the frames very much, but instead the sectional cases, it will not be greatly to our advantage to have the frames as readily movable as are the L. frames. On this account a very simple case is all that is necessary to hold the frames—a case without ornamentation, clamps, screws, or any thing of the kind. Neither do we want a complicated bottom-board; but all the parts of a practical hive of this nature should be, *and will be*, made of only a few pieces, and all very plain, and easy of construction.

The frames can be supported in the sectional case on strips of sheet iron cut 5-16 wide, and as long as the case is wide inside, the strips to be inserted in thin saw-cuts made 5-6 of an inch from the inside lower edges of the ends, and to enter the wood only 3-16 of an inch. This construction will give a proper bee-space under the frames, which should extend to the top of the case. The width of the end-pieces of the frames should be 1⅜ in., and the thickness ¼ in., making a closed-end frame to rest on the sheet-iron strips. The width of the top and bottom bars should be the same, and may be ¾ x ¼ inch in thickness.

Here let me call the attention of bee-keepers to the comparative cheapness of these frames, if dovetailed at the corners, to those in common use. They need no nails, and a set of 14 for one hive can be put together in a few minutes; and as they can easily be made very accurately, they will always fit nicely in the cases. The length of the frame might well correspond with the 4¼ x 4¼ sections now so popular. The outside would therefore be 17 inches long, and, if made just 5 inches deep, it will take one-half of a sheet of foundation, cut the regular size for L. frames. The frames can be taken out of the cases very readily, since, being very shallow, the cases can be set on end, and the frames pushed through, one or more at a time. Hence the worthlessness of all clamps to hold the frames in place will be apparent.

Again, if we are to handle hives rather than frames we can see no advantage in having so many frames in each case. I think we shall find seven enough, though many may prefer eight or even nine frames to the case. It will then be very light; but to further lighten it we would make the sides only ⅜ thick, and the ends ⅝, and make the usual hand-holes in the ends, or nail cleats across the ends a little above the middle line to handle them by.

The bottom-board, we would make out of half-inch stuff, with a cleat across each end, of one-inch stuff, the rear piece to be two inches wide and the front five inches. The board is to be cut 1⅛ inches shorter than the hive is long, and the wide cleat nailed across two inches from the end. This would give an entrance across the front of ½ inch. If blocks are nailed on each side, to go under the front corners of the hive, ordinary entrance-blocks can then be used.

Sectional hives, containing only seven or eight frames in each section, will be so light that we shall find it an easy task to carry them back and forth from cellars in wintering, where they can be placed under our full control, and wintered in a scientific manner, which we shall never be able to do in outdoor wintering, where we can not regulate the temperature at will. Only one of the sectional cases, well filled, will be necessary for each colony for the winter.

To operate a sectional hive of shallow frames successfully we shall need a honey-board with strips of perforated zinc set in thin saw-cuts, made in the edges of the slats compassing the board. This construction and use of perforated zinc is my invention, but it is free to all to use. As any kind of a section case or super can be adjusted to this hive, every bee-keeper will be expected to use his favorite.

The capacity of two of the sectional brood-chambers will about equal the eight-frame L. hive, but many would prefer to use three of the parts in building up for the honey-harvest. The frames alone are made to reverse, but we shall need to reverse them but once, and that simply to get the frames filled out with comb plump to the sides all around. Ordinary six-inch boards can be split and dressed to three-eighths for sides of the cases, and we shall have no trouble to get whole boards wide enough for the bottom and covers, and yet there will be ample room for top storing on the hive. For a *very cheap hive* we shall never get a cheaper; and a better hive for *large results* may not be possible.

It will hardly be necessary to add, in conclusion, that this hive is not patented or patentable, except in one or two features, which are my inventions, and are hereby freely given to the public.

Since we received the above, the following, also, came to hand from Dr. Tinker:

I have sent you a brood-chamber by express. It weighs complete, two tiers of frames, only 6½ lbs., and the complete hive will weigh about 15 lbs., and I think it is heavy enough.

As I wrote to you, I shall make a specialty of sections, and do not care so much about hive-making. You can therefore do what you like with it. For myself, I am now more favorably impressed with the hive since making a few of them than before I wrote the article. I further believe that the frames will prove to be more readily movable than I had anticipated. The hive is exactly right width for a section 1⅝ wide, with or without separators, but I shall use upon it a section 1½ inches wide.

The secret of working sections without separators is a *narrow case*. You will now see why I prefer only 7 frames wide in the hive. I believe that these little narrow hives and cases possess more merit than will be readily granted, and that they have a future.

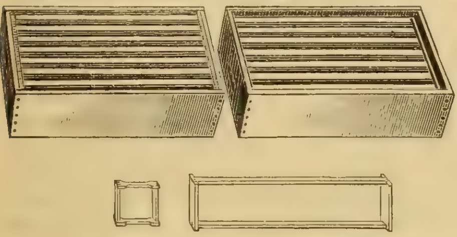
Where the sections are massed together in a narrow case (which is alone practicable without separators) of 4 or 5 sections wide, the side passages have the same advantages, of course, that exist where separators are used.

If, however, we are to *invert* the sections, then a wide frame, constructed exactly like the brood-frames, but a little wider, and to be held in the super in the same manner, seems indispensable. For I believe that, under many circumstances at least, it is impracticable to invert whole cases of sections at a time when any advantage is to be gained from the practice; but if the sections are in wide frames we can usually invert them, one or more at a time, as may be safe to do, the danger being that the combs will lop over sidewise, as they are exceedingly tender before they are capped over. My opinion is, that it will never pay to invert sections. If a case is made to hold wide frames, it will require to be just ½ inch longer than the case described, and the cases to hold the brood-frames, as well as the frames, will require to be ½ inch longer.

G. L. TINKER.

New Philadelphia, O., Feb. 20, 1886.

The shallow brood-chambers sent us by Dr. Tinker are of such extremely nice workmanship, we have taken pains to have cuts of them made. By the way, the doctor's letter is a consideration of the principle suggested by friend Heddon, though he doesn't say so. You will notice he suggests making the hives still narrower than eight frames; in fact, so narrow as to contain only seven.



A HIVE COMPOSED OF NARROW, SHALLOW BROOD-CHAMBERS.

The brood-chambers shown above are 10⅝ inches wide, outside measure. As the boards comprising the sides are ⅜ inch thick, these chambers are 9⅞, inside measure. The frames are about 1⅜ from center to center, therefore seven fill the chamber. The end-pieces are ⅝ inch thick. The frame shown is composed of strips ¼ x ¾. The end-pieces are ¼ x 1⅜. The doctor thinks they do not need nailing. We would nail them both ways with slender nails, securely, in order that they may never pull to pieces, for we may have considerable trouble when the time comes to take these little frames out, if such time ever does come, after they once are nicely filled with combs. In the figure on the left, the frames are shown flush with the top of the hive. The figure on the right shows the same inverted, where the frames are ¼ inch below what is now the top edge of the hive. They are held by a little strip of iron driven into a saw-cut in the usual way. Whether or not these arrangements are ever going to be used in place of movable frames, is the question. I suppose there is no further necessity of debating whether any one has a right to use this arrangement, after reading the letter on page 211. And while we are about it, perhaps it may be as well to say there seems to be no use in *discussing* the matter any further.

REPLY TO G. M. DOOLITTLE.

SEPARATORS, AND WIDE FRAMES TO HOLD SECTIONS.

I HAVE read Mr. Doolittle's quotations on page 171. My correspondence is so great that I must be excused from replying, sentence by sentence. Mr. Doolittle's quotations are all confined to 1881, except the last two, to 1886. He will find just the reasons he asks for, in my writings, between those dates. I have before explained fully how I made my mistake in my first experiments with separators.

Many of Mr. Doolittle's questions are answered in my chapters on hives, and again by him in the fifth paragraph in his article in *A. B. J.* for March 10, 1886. He says in one place I lay the blame to glue; and in another, to two-story wide frames, and wishes to know which is correct. I answer, both; two-story wide frames are glued much worse than those one story deep, especially when tightly pressed with our thumb-screws, as we describe in our book. But for my desire to reverse my sections, I now think I wouldn't use wired frames, whether I used separators or not.

We overcame the propolis question by using shallow wide frames tightly pressed with thumb-screws. I made some mistakes regarding separators in 1881, and the same diligence with which Bro. D. has found them will aid him in finding my admissions and corrections, made long before I wrote the book, "Success in Bee Culture."

Friend Root wrote as though in my book was the *first* place I had spoken in favor of wide frames and separators. Friend Hutchinson corrected him.

Dowagiac, Mich. JAMES HEDDON.

OUR OWN APIARY.

Boiling-Point of 212° Reached with the Solar Wax-Extractor: Experiments with.

WHY THE BEE HATCHES WITH HIS HEAD TOWARD THE CAPPING.

ON page 226 of this present number I am asked whether the bee larva absorbs its food, or whether it receives it by means of a mouth; also why the bee does not starve when it hatches with its head toward the capping; i. e., turned from the base of the cell where the food is supposed to be. In answer to the first question, I will say that a few of the lowest forms of animal life receive their nutriment by absorption, and are generally parasitic. The larva of the bee, though by no means as perfect as the mature bee, yet is possessed of a mouth, rudimentary digestive organs, and a means of respiration. If you take notice you will observe that the young larva will consume a large quantity of food; and were it not for the frequent visitations of the nurse-bees the tiny grub would soon starve. Generally, as we know by sending larvæ by mail, the quantity of bee-jelly will not last the grub much more than 24 hours, if taken from the hive. The larvæ of insects in general are voracious eaters, and the amount of food that they will consume in proportion to their size, as compared with an ox, is enormous. The larva of the bee is no exception to the rule. Indeed, it is quite necessary that the grub should gorge itself during the larval period; for, as we shall presently see, it will need the nutriment derived therefrom for a period of rest.

Now we come to the consideration of the second question; namely, Why does the bee hatch with its head toward the capping, and how does it obtain food, if any, when in the pupa state? From observation and facts which I have been enabled to glean, I am led to believe that the bee, during its pupa state of development, like other insects of its kind, remains in a quiescent condition, during which it takes no food. Indeed, confined within the narrow limits where nature has placed it, without any surplus room in which to reverse its position, how could it turn its head in the direction of the food? We know that the bee hatches with its head toward the capping, and in this position remains upward of 12 to 14 days. During this time we will suppose that the grub as described on page 848, last year, has just relined his cell, covering up all remnants of food, together with all refuse matter, and that his compartment is nice and clean. In the process of development the unsightly grub is distinctly divided into three separate hardened segments at the same time that legs and other organs begin to appear. If in a day or so before the time of hatching we should break open the cell, we should find an ivory-colored bee, and we might or might not detect signs of life; at any rate, we should find it in a state of comparative quiescence. The exterior covering of the bee has become hardened and shell-like, which would make it quite impossible to get any food at the base of the cell, even if there were any there. The bee has his head toward the capping, because, like the chicken in the shell, he is the proper one to decide when he is mature enough to hatch; but were his head toward the base of the cell it would be quite impossible to liberate himself. The caterpillars and silkworms, besides the larvæ of other insects as well, become quiescent when in the pupa state, as we learn from good authority on the subject; and bees would be no exception to the rule. So if we examine all these peculiar phenomena we shall find a cause, and generally analogous instances in other insects.

EXPERIMENTS AGAIN WITH GREEN'S SOLAR WAX-EXTRACTOR, IN WHICH THE BOILING-POINT, 212°, IS REACHED.

March 15.—To-day begin rather warmer than usual, I decided to experiment further with the solar wax-extractor—the outside temperature in the shade being 65°. The extractor was arranged in a suitable position; and, after a lapse of an hour or so, I looked in. The mercury was above 180°; yes, the temperature was actually 213°, or a trifle above the boiling-point. I think we shall have to admit that eggs boiled by the sun's rays is a thing quite probable—indeed possible. If the weather is favorable, and I don't have "bad luck," I will report in regard to sun-boiled eggs versus those boiled by the other method. But, wait one moment; a difficulty confronts us at the outset. The water in the extractor will have to be heated from its surface; whereas, water in a kettle, by the ordinary means, is heated from its base by *convection;* i. e., the atoms are transmitted from one part of the water to another. It is laid down in physics, that water reaches its maximum density at about 39°; when the water is warmed above this point it is expanded, and, in consequence, is lighter. In the wax-extractor, the water will of necessity be heated at its surface by the action of the sun's rays. As this stratum of water is lighter, theory says it will stay on top, and not mingle with the water below and it thus will be heated very slowly. When we go in bathing, after wading out to our necks we often find a cold stratum at our feet, when the water within a foot or two of its surface is warm, having been made so by the action of the sun. This water, as it is less dense, is lighter, and does not sink. In regard to sun-boiled eggs, we will see what practice has to say later.

OUR OWN APIARY.

Our bees are still in splendid condition—only three lost from the whole; but we had reason to suspect these would not winter, one being the Holy-Land colony that I have already referred to, and the other two when put up for winter were queenless. We are thus much better off than we were a year ago at this time, when we had a loss of six instead of two as now. ERNEST R. ROOT,

CIRCULARS RECEIVED.

C. M. Dixon, Parrish, L.I., sends a 4-page list of supplies in general.

C. Weckesser, Marshallville, O., sends a four-page sheet—bees and strawberry plants.

J. P. Moore, Morgan, Ky., sends a 4 page list of bees and queens.

Rev. William Ballantine, Mansfield, Ohio, sends us a 16-page price list of bee-supplies in general.

Simon P. Roddy, Mechanicstown, Md., sends us an advertising sheet of bees and queens, a specialty.

Ernst S. Hildeman, Ashippun, Dodge Co., Wis., sends an advertising sheet of farm produce and bee-supplies.

W. W. Bliss, Duarte Cal., sends a 12-page circular of apiarian supplies; specialty, foundation.

S. Valentine & Son, Hagerstown, Md., send a 20-page price list of bee-supplies.

Frank A. Eaton, Bluffton, Ohio, sends us his advertising card and price list of bees and queens

D. A. Fuller, Cherry Valley, Ill., sends his advertising sheet, hives a specialty.

J. W. K Shaw & Co., Loreauville, La., send their 4-page list; specialty, early Southern queens.

E Kretchmer, Coburg, Iowa, sends a neatly gotten-up price list of 27 pages, hives and Italian bees a specialty.

E. W. Greer, St. Mary's, Mo., sends his advertising card—poultry and hives.

A. J. Norris & Co., Cedar Falls, Iowa, send their 4-page sheet; specialty, Italian and Carniolan queens.

E. M. Yeomans, Andover, Ct., sends a 4-page circular; queens and nuclei a specialty.

Reynolds Bros., Williamsburg, Ind., send a 16-page circular of bee-supplies in general.

R. M. Morrill, Plymouth, Ind., sends an 8-page circular; specialty, small fruits.

Sumner and Prime, Bristol, Vt., send a 16-page price list of bee-supplies.

H. R. Boardman, East Townsend, Ohio, sends an advertising sheet; specialty, choice comb and extracted honey.

Geo. Wheeler, Norwich, New York, sends a 10-page list, hives a specialty.

G. B. Pickering, Fisher's, N. Y., sends a 4-page sheet; specialty, seed potatoes.

Earl Clickinger, Columbus, O., sends an advertising sheet of bee-supplies in general.

A. F. Stauffer, Sterling, Ill., sends an 8 page circular—bee-supplies.

J. W. Clark, Clarksburg, Mo., sends a 15-page circular, 8 pages of which is a diary for the registration of swarms and their increase.

O. H. Townsend, Alamo, Kalamazoo Co., Mich., sends advertising sheets of bees and foundation a specialty.

Bostwick & Ashley, Medina, leave with us their "Egg Bulletin" for 1886; specialty, poultry and eggs.

James W. Tefft, Collamer, N. Y., sends a 4-page circular of the "Queen City" bee-hives as a specialty.

Dr. J. P. H. Brown, of Augusta, Ga., sends us his 15th annual catalogue, of 20 pages; hives a specialty, such as are adapted to the southern climate

J. D. Goodrich, East Hardwick, Vt., sends us a sample of his white-poplar sections, with a two-page circular and samples of comb foundation, very neatly packed inside the section blanks.

Among the circulars and books recently printed at this office we notice the following:

B. J. Miller & Co., Nappanee, Elkhart Co., Ind., a 16-page circular of bee-supplies in general.

G. K. Hubbard, Lagrange, Ind., a very pretty 10-cent bee-book. It has 64 pages in all, the first 30 of which are devoted to a considerable amount of valuable information, condensed in a small space. The remaining pages comprise a description and price list of the Hubbard bee-hive. Mr. Hubbard will furnish the book at the price named above.

A BEE-JOURNAL STARTED IN AUSTRALIA.

VOLUME I., NO. 1, of the *Australian Bee-Keepers' Journal*, is quite a pretty little magazine, published at Melbourne, Australia, at 6 shillings a year, or 6 pence per copy. The *Journal* is well gotten up, the paper is nice, the printing is nice, and the matter is well selected. We wish them Godspeed.

IMPROVEMENT IN BEE-HIVES AND FIXTURES.

NO NEED OF DEMORALIZING CHANGES; SIMPLICITY HIVES EASILY CONVERTED INTO REVERSIBLE ONES.

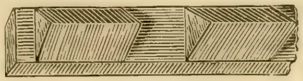
FRIEND ROOT, we gather from what has been written on this subject of improvement in hives, that what is most needed to accomplish the improvement are the following new and desirable features: 1. The easy and quick reversal of the brood-combs when necessary; 2, Permitting the use of a practical honey-board between the brood-frames and the surplus; 3, Whenever thought necessary, allowing the easy and rapid reversal of the surplus honey, either when in frames of comb or in sections above; 4, Allowing the use of separators between the sections when using them in the case system, and on the tiering-up plan.

We know that there have been given, from time to time, a great many methods, and recently an invention, whereby these things may be accomplished; but it seems that they all meet with more or less opposition, on the ground of the demoralizing changes they would of necessity bring about if they were generally adopted. After much careful study and thought upon the subject, it seems to us (and we doubt not our bee-keeping friends will generally agree) that if the addition of the above-mentioned valuable features could only be made to our time-honored movable-frame hives in the personality of the L. and Simplicity, at the same time retaining all of their best features, which have been found to be so valuable, after long years of service and experience, it would be "a consummation devoutly to be wished;" and although at first thought it seems hardly possible, nevertheless we predict that it will not fail of consummation. And now, friend R., with this end in view, if you will kindly allow us space, we will try to make it plain to yourself, as well as our bee-keeping friends, how it is possible to convert a Simplicity hive (those already in use) into a reversible hive, possessing all the desirable features alluded to above, and at the same time doing it without taking it apart and building it over again, and that, too, at so little trouble and expense it could not possibly be considered demoralizing to think of making the change, taking into consideration the many and great advantages to be gained. This is done in the following manner:

Take a Simplicity-hive body, place it upon a circular-saw table, having set the guage at 9½ inches; run it through and cut away the bevel portion at the top, all around; this should leave the top of the hive on a level with the tops of the frames. Next nail on a light frame, or collar, made of strips of wood ½ in. square, size 16×20¼ outside measure, to take the place of the beveled portion removed. This done, you have a Simplicity that will reverse ten hanging frames (or a less number, even with division-boards) without having any alteration to make in them, by simply turning the hive bottom side up, provided the frames are supported from falling out by means of two strips of wood ½ in. thick, ⅞ in. wide, and 15 inches long, laid across them near their ends, and made fast to the offset in the sides of the hive, these being, as we mentioned before, on a line with the tops of frames.

The strips used for this purpose are best made of basswood, and according to the following diagram, only the beveled portion then resting upon the bottom-board, thus furnishing less surface for propolizing. They also would be much better if made of cast metal.

These strips not only hold the frames in their proper places while the hive is being turned over, but, resting upon the bottom-board, by the weight of the hive they press the top-bars firmly against the rabbet, thus preventing the bottoms (which are now the tops) from toppling or leaning together. A Simplicity hive thus treated, makes practically the same hive we are now making and using, the past season's experience with which has given us great satisfaction, an illustration of which can be found on page 771 of GLEANINGS for Nov. 15, 1885, to which please refer, as it will greatly assist us in the further explanation.



STRIPS OF WOOD TO LAY ON THE FRAMES.

Now, with our Simplicity bodies made reversible they will manipulate in all ways the same as the Ideal reversible bee-hive there shown, which is only a modification of the Simplicity, and they will now admit the use of a wood-slat honey-board like the one shown in the cut. This honey-board is reversible, is 15 in. wide and 19 in. long, and has 60 openings like those in a section box, only not so wide, being scant 3-16 in.; and when placed in position on the hive it gives two bee-spaces of ⅜ in., one above and one below. Now, a Hutchinson, or a Heddon honey-board either, could be used, provided it is made wide enough for a ten-frame hive.

Our reversible Simplicity bodies are still interchangeable, and can be tiered one above another, just as they could before; and having a honey-board between, which prevents the upward building of comb from fastening the two sets of frames together, they are much more easily removed when filled. The upper story can also be reversed, the same as the lower, and will reverse metal-cornered Simplicity frames as well as all-wood top-bars, or both kinds together. Half-stories, if they are made alike at top and bottom, to hold the sections and separators in single-tier wide frames, can also be reversed over the brood-chamber, provided the tops of wide frames are made the same width as their bottoms; however, we do not recommend the use of wide frames to hold the sections, either in single or double tier, in order to be able to use separators, for we have a much better way of doing it.

This brings us to consider our reversible cases, to be used over our newly made reversible Simplicity body, to hold the sections and separators (see illustration above referred to); and from practical test we can safely recommend it as being by far the easiest, simplest, and best method, thus retaining all the valuable features of the case system, as taught by friends Heddon and Hutchinson, besides adding to it the use of separators, and permitting the reversal of all the sections at one operation.

The case holds 33 1¾-inch sections, without any separators, or 30 1⅞-inch sections with separators between them—not short ones either, but long enough to reach across three section boxes; nor do they have to be nailed to any thing as separators are when used in wide frames—a very big advantage, as any one trying it will discover. The cases are not thin-walled, as the Heddon case, nor do they need the outer covering, as does the Moore case. They are 16×20¼ inches, outside measure, and fit over a Simplicity hive exactly. The ends are of ½-inch lumber, and the sides of ⅞-inch. When they are placed on the hive, a honey-board goes between, and they can be tiered up, one above another, the same as the bodies. We believe we have written to you how this plan of reversing frames and sections can be utilized in a chaff hive.

And now, having made it plain (as we think) how all these new and valuable features may be added to the hives we already have in use, with but little trouble and expense, by only slightly repairing them, we will mention only one of the many advantages this plan presents above any other method yet offered. This, of course, we consider the most important of all. It is the retention of our good father Langstroth's movable hanging-comb frame, that we all love to manipulate so well. If, however, we have not made it sufficiently plain, we shall be pleased to try again. **HEMPHILL & GOODMAN.**

Elsberry, Mo., Feb. 12, 1885.

Thank you, friends, for the caution about being in haste to drop our old hives and take up new ones. I have already reversed Simplicity hives on a plan similar to the one you advise. Instead of sawing off any thing from the top edge of the Simplicity hive, however, I would make a frame such as would be obtained by taking a common Simplicity cover, and sawing half an inch from the lower edge, clear around. This will go right on the hive, and may be bradded fast. The strips to hold the frames in place I would make of tin, folded much like an ordinary tin rabbet, only being half an inch on each edge. Push these down on top of the frames, leaving the sharp edges of the tin sticking up. A nail driven into the side of the hive, so its head lies snug down into its channel, with folded tin, will hold it in place so the hive may be inverted. We found, however, that a whole Simplicity hive was pretty heavy; and half-depth frames would doubtless be more easily handled, and would work nicer. See the article from Dr. Tinker, on page 203.

THE STINGLESS BEES OF MEXICO.

MORE ABOUT THEM.

THE statement of John L. Gregg, about the small bees of Mexico, is by no means a new thing. These bees are well known to entomologists as the honey-bees of the tropics, which are very small, have no stings, and live in very large colonies. They are known as *Meliponæ*. The wings are shorter than the abdomen, and the mandibles are not toothed. They are found only in South and North America, and not in the other continents. There are several species of them. Some build their combs in hollow trees, some in banks, and others suspend their nests from branches of trees. One variety builds clay hives, and its honey is said to be excellent. It is not probable that these bees would thrive in our cool climate.

MICA FOR BEE-VEILS, ETC.

I send you a sample of our mica, which, as you will find, can be split with a knife into very thin sheets, which I think would make excellent eye-pieces for bee-veils, also for observation-holes for hives. This is only a small size. It can be cut with scissors with ease, and pierced with a needle so it can be sewn. Plates 6 or 8 inches square can be procured; but this size is dear, on account of the demand for it for stoves. The small sizes, like the sample, can be procured quite cheaply, for $2.00 a pound, about; and a pound would make a large number of sheets. This mica is very abundant here. It was mined by the aborigines who built the great mounds in Ohio and other parts of the West, in which plates and sheets and ornaments of it are found; but as a large quantity of rock has to be moved to get to the mica, it has a market value of from $4.00 to $10.00 per pound, for merchantable sizes. **HENRY STEWART.**

Highlands, N. C., Feb., 1886.

Friend S., we are much obliged for the additional facts you give in regard to these bees; and although it may be true that they will not live here in the North, what is to hinder sending our boys and girls down to Mexico to look after them? Who will volunteer to see whether it be not possible to produce honey that can be profitably shipped north, from these new bees?—In regard to the mica, it has been several times before our people, and bee-veils have been advertised with mica fronts. Many thanks for your beautiful specimens.

BEE-TALKS.

NO. 2.

MAN is a mimic, it is said; and this is true to a large extent. We do as we have learned from others. But I find that we all have some ways of our own. No matter how well we may have learned our trade or profession, we will do some things differently from others, or the way we were taught to do. It is all right that we should do so. It is the only way we, as a whole, make any improvements. It is those departures from the old ruts that result in our valuable inventions in every thing. Our most successful bee-keepers differ very much in their manner of management of their bees. Almost every one has a way of his own, and I have sometimes thought I was an odd one, as I have so many of my own notions. Still, I have learned and practice a great deal that I have learned from others. I take the *A. B. J.* and GLEANINGS, two very valuable papers, and I would not do without either for three times their cost. But the best book that I have is my bees. They are a great study, and I am all the time learning something new about them.

I have been the owner of more or less bees for over forty years (I am now 62), and what I say or do must be done soon; and if I write any thing that would be misleading to beginners, I ask the old heads in the bee-keeping fraternity to correct me. But we must bear in mind that location has a great deal to do with results; and the more bees one has, the more he has to change his manner of operations. Plans that would do for ten or twenty colonies won't do for one hundred or more.

Beginners in the bee-business should do one of two things—either start with a few bees, or work two or three seasons with a good practical bee-keeper, one who has made bee-keeping a success, and has handled a large number of colonies; and then, in connection with the work, read all the standard works on bees, including the bee-papers. I think the last plan the better of the two.

I believe that bee-keeping can be made a success if the party engaged in it has a liking for the business, and starts in a good location. But the bee-business is not all honey. I have found, in my experience, a great many pull-backs and losses, and many things that did not come up to my expectations but I have blundered along until I have learned something about the bees and about my locality, etc. In my remarks I wish to speak of my management, and my mistakes.

Bee-keepers as a rule, don't like to tell their blunders. They "blow" about their great success, big crops of honey, and figure up every thing at the highest price, and make a big show in figures. Perhaps the next year their success is in the little end of the horn—had bad luck; bees winter-killed, spring-dwindled, poor honey season, etc. Not a word said now. So the A B C class get only the bright side, and are led to think that bee-keeping is a big thing, and they go in heavily, only to end in failure and disappointment.

HOW DID I EVER COME TO BE A BEE-KEEPER?

Why, I just blundered into the business. I always had a liking for bees and honey. I tried hard to be a farmer. I went to Iowa 30 years ago, bought 200 acres of land on the prairie; stayed six years; then the war broke out, and at first there was no price for any thing I could raise on the farm. We had some relatives here in Platteville, so we left the farm and came here to visit; stayed a year, and then went back to the farm again.

When we got here I had to do something for a living, as my labor was about all we had to depend on to support myself, wife, and one little boy, then five years old. About that time I saw an advertisement, "Agents wanted, to sell Metcalf's Bee-hives." I took the agency, got a sample hive, and made the hives myself. At that time almost every farmer kept a few swarms of bees. The hives sold for $2.50 each; the patent to use them, $5.00 for a farm-right. I had all I got for hives, and half for the patent. I soon made enough to buy the county-right, and then I bought two more counties. I took some bees in trade, and that is the way I got started.

The hive was a frame hive, 12 x 12 inches, and 17 inches high; used 8 frames standing on the bottom, It had a movable front. I made them single for one colony; double for two, and quadruple for four colonies, all single-walled hives, no chaff hives then, nor extractors. I worked my bees for comb honey in large boxes, 30 lbs. or more. I soon divided my boxes down to 3 lbs. Honey sold then from 25 to 30 cts. at home. I kept increasing slowly until the fall of 1871, when I had 123 colonies of bees. I already had them in three apiaries. All old veterans will remember that winter of 1871 and '72. In the spring I had 20 colonies left alive.

The next fall I started in the winter with 50, and that winter was a hard one. The spring of 1873 I had 14 colonies alive. Then I made up my mind that my hive was too small, so I commenced to make larger hives. I made them 13½ x 13½, and 22 inches high, inside measure. I used 9 frames, and made them quadruple, or, as they are called nowadays, tenement hives, holding four colonies, but at that time I made them single-walled. I changed my 14 colonies all into the large hives. My stock of old hives was used up for kindling-wood. There was no sale for hives, as all the bees in the country about here were dead.

Now right here let me mention one of my blunders. I got me an account-book, and kept a record of just what was done with every individual colony, but I failed to give my number of colonies in the spring and fall, and amount of honey taken each year—in fact, no general management, which would have been of more value for reference. But I make out this much: That in the fall of 1880 we had 220 colonies; in the spring of 1881, we had lost all but 72. We had one yard of over 60 colonies, that went down to 3; cause of the loss, too windy a location, very hard winter, and we extracted too close late in the season.

The year of 1881 was a poor season for honey, but we increased our 75 colonies to 157 in the fall, and took 2000 lbs. of honey, all extracted, and had our bees fixed up in splendid order for winter.

The winter of 1881 and '82 proved to be an open, warm winter. Of the 157 in the fall, we had 155 colonies in the spring, which we increased to 295 in the fall, and took 13,000 lbs. of honey.

The spring of 1883 we had 211 colonies in five yards. The loss was almost all from desertion in the spring. From the 211 colonies in the spring of 1883 we extracted 22,037 lbs. of honey—an average of 104½ lbs. per colony, spring count. I failed to record the number of colonies in the fall of 1883.

The spring of 1884 we had 291 colonies. From 287 colonies we extracted 31,283 lbs. of honey; comb honey, 206 lbs. from 4 colonies—an average of 109 lbs. for the 287 extracted, and 51½ lbs. average of comb honey from the four ran for comb honey. We went into winter quarters with 455 colonies.

Last winter was a hard one, and the spring of 1885 found us with 321 colonies—a loss of 134. From these 321 we extracted 33,086 lbs. of honey, and increased the bees to 510 colonies. Our average per colony this year was 103 lbs.; but owing to so much wet weather at the close of the basswood season, and no fall honey, we had to feed back to the bees 6114 lbs. of honey, to give them enough to winter on. That left us 26,972 lbs. after feeding back. Our average would be 84 lbs. per colony, spring count.

I find it hard to tell just when to quit taking honey, and get all the honey we can, and leave them enough for their winter stores. In this locality the basswood is the last thing that gives us any surplus. We try to time it so that the bees will have a good supply for winter out of the basswood. This year, when the basswood was half through, we commenced as usual to leave in full combs of honey in the back-side of the hives, leaving in more and more every day. The last day we extracted we left in one-half of the honey. The next day was a rainy day, and the next five days were wet, drizzly weather, and the basswood season was over. The bees were short of honey for winter. We waited three weeks and then went to feeding. We fed one yard at a time until all were fed. We fed the last honey we extracted, and fed all but one yard; that one had enough, and it was the next yard in rotation to extract, but we did not get to it, on account of the rain.

We use the pepper-box feeder, quart size. It holds three lbs. We put two on a hive at a time, and fill them up again in two days. We fed one yard of 100 colonies six feedersful each—18 lbs. each, or 1800 lbs. for the 100 colonies. The other yards were fed, some 18 lbs., some 12 lbs., and some 6 lbs., according to their wants. We did not go to the trouble to examine all the hives in a yard. We would open about 10 or 12, take a look at them, and make up our mind how much they wanted, and then feed all the colonies in the yard alike. Be sure to give them enough. It is much better to feed in the fall than in the spring.

Now just a word about hives. I very much prefer aq uadruple hive, four colonies; then have it doubled-walled, and fill in between the walls with chaff. We are making and using my improved Metcalf hive and some Langstroth hives; but for our own use we put the L. hive in a quadruple form, two or more stories high, lined all around the out side with a chaff cushion. The cushions are put inside of the hive. We winter all our bees outdoors, and we have to give them all the protection we can.

Platteville, Wis. E. FRANCE.

Thanks, friend F., for the valuable facts you give us. The matter you mention in regard to extracting just enough and no more is indeed a fine point. We once had a similar experience. During the last of my extracting, the robbers got so bad we stopped, and the last half of our apiary was not finished at all. They wintered nicely, while the half that had been extracted, a good many of them starved, and others had to be tinkered with. Now, let me suggest that taking out heavy combs and setting them away will fix this nicely. I know it is some trouble, but I think it is more trouble to throw honey out of combs, and then feed it back again. From the experiments recently given in feeding back extracted honey to get sections finished, it looks as if from one-fourth to one-half of your honey is lost where you throw it out and then feed it back, compared with the plan of just lifting full capped combs from the hives and setting them back when needed. I may suggest to our readers, that friend France is the one who gave us the idea of the pepper-box feeder, shown in our price list, page 13. I am glad to hear that somebody is using tenement hives, and likes them.

NOTES FROM THE BANNER APIARY.

NO. 75.

MR. HEDDON'S NEW HIVE AND SYSTEM.

WHEN Mr. Heddon explained to me, a year ago, the beauty and originality of his new hive and system, I was fairly captivated. I then felt, and *still* feel, that his invention is second only to father Langstroth's. I firmly believe, in fact I *know*, from actual experience with the hive, that Mr. Heddon has given us a movable *hive*, in the sense that we before had a movable *frame*. I *know* that almost every manipulation in an apiary run for honey can be performed without removing a single frame. It is a grand step. Although well satisfied of what could be done with his hive, Mr. Heddon did not patent it until he had proved, by *two years'* actual work with it, that it was worthy of a patent. Naturally, Mr. Heddon expected, when he made public his invention, that there would be some "pooh-poohing" done; and then, when its value was finally recognized, he expected to hear the assertion that it was not *new*. He was mistaken in only one particular, and that is in the amount of "pooh-poohing" that would be done. The cry of "worthless" was scarcely breathed ere it died upon the lips that uttered it, and was dropped for the one of "Oh! it's old, it's old, it's *old*"—the very same cry with which father Langstroth was "dogged." Now, all bee-keepers rise up and call him blessed. Let us not repeat the mistake of our fathers.

Let us not first *assume* that Mr. Heddon's hive is "old," and *then* ransack the Old World as well as the New for proofs of our assumptions; let us not *desire* to arrive at a certain conclusion, but rather to learn the *truth*.

Mr. Heddon does not claim to be the inventor of shallow frames, of reversible frames, of reversible hives, nor of "thumb-screws;" but he was the first to invent and make public the construction of a *brood-chamber*, not "*hive*" (here is where those who cry "old," "old," make their mistake) in two horizontal, separable sections. While he *claims* them only when invertible, he has a *moral* right to them in any shape; and let any supply-dealer now advertise Langstroth brood chambers in two horizontal, separable, interchangeable sections, and the moral sense of the community will at once recognize the theft. That Mr. Heddon had in mind the fact that many advantages would accrue from using shallow Langstroth frames, and interchanging them, is shown by the third paragraph on qage 96 of "Success in Bee Culture." It reads as follows: "Having the brood-chamber in two horizontal sections, or parts, admitting of interchanging the upper with the lower portion at will, for the purposes specified, placing the part below containing the most honey, putting both in a new position, produces many of the same results and advantages given us by inverting. . ."

Those who are thinking of *evading* Mr. Heddon's patent by using half-depth Langstroth frames should know that they are losing many advantages by so doing. A single section can not be inverted, which is an advantage when only one case is used, as in contracting the brood-nest. The frames will never be solid full of comb. Queen-cells can not be so easily clipped without removing frames, and the bees can not be shaken from the case, as the frames are loose.

I am well aware that many of our inventions are the result of many minds. It is seldom that one inventor makes such a jump as did father Langstroth; but each space covered by a "little jump" belongs to the man who cleared it, and is patentable. Perhaps many of the readers of GLEANINGS do not know exactly what Mr. Heddon has invented. For their benefit I will give some of his most prominent claims.

1. Arranging comb-frames within a case which is a bee-space deeper than the frames, in such a manner as to hold them securely at will in a central position, leaving half a bee-space on each side, or readily shifting the whole bee-space to either side.

2. He was long since the inventor of a honey-board containing one or more bee-spaces, or parts thereof, on one or both sides, and he *now* claims such a board when used in *combination* with a hive whose *brood-chamber* is constructed in two or more horizontal, separable, and interchangeable sections.

3. The use of a set-screw, when *combined* with closed-end frames, in a case, *substantially as he uses it*.

4. The projecting tin rests, when used in *combi-*

nation with the set-screws, frame, and case (any claim holds its equivalent), and these tin rests are a grand thing in *combinaton* with the screws, wedges, or levers, or anything of the kind.

5. The *combination*, with said comb-frame cases, of a cover containing a bee-space, or partial bee-space in one or both of its surfaces.

6. The *combination*, with one or more invertible-hive sections, of the bottom-board, arranged as described and illustrated.

And now comes a broad original claim.

7. In a bee-hive, a *brood chamber*, composed of two or more horizontal, separable, interchangeable, and invertible sections, each section containing within itself a set of brood-comb frames whose depth is one bee space less than the depth of the case.

There is one or two more less important claims; but the above are enough to show our intelligent public that no one can make a hive half as good as Mr. Heddon's without infringing.

I should like to have it explained how it can be that things *dead* can be "just like" valuable living things, just born, that everybody now wants. Why did they die? There *must* have been a difference. There *is* a difference, and it is this: Before modern beeculture divided hives into two radically different apartments (brood and surplus), tiering sections were suggested; but all these ideas perished, and have no more to do with invalidating Mr. Heddon's patent than has one of the lost arts. In other words, making *hives* in horizontal sections is *not* new; but the making of a *brood-chamber* of "two or more horizontal, separable, interchangeable, and invertable sections," *is new.*

W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich.

Friend H., it may be I have not gone deep enough into the matter; but to my comprehension it seems to me that the following answers completely your last paragraph and pretty much all of the above article.

KRETCHMER'S ALTERNATING HIVE.

THE PRINCIPLE NOT NEW; IN USE AS EARLY AS 1865.

IT seems to me that James Heddon's claim on his new hives is rather sweeping at this late day. His hive is in substance the same as my "Alternating hive," made by me in 1865; patented July 23, 1867, No. 67,123, and given for free use to the public about ten years ago.

It consisted of three equal tiers, each tier about 7 inches deep, and containing each 10 frames. The upper tier was used for surplus honey, and the two lower tiers for brood; after the two lower tiers were filled, and the surplus-honey tier added, the two brood-tiers were "alternated;" that is, the middle tier was placed at the bottom, and the bottom one placed in the middle, so that by this arrangement the center of the brood-nest was brought close to the surplus-honey chamber, into which the bees did very readily enter. Combs had frequently been started by having this surplus tier at the bottom for a short time; the top of the original brood-nest was by this alternating process brought in the center, and most of the honey removed to the surplus-chamber; and for swarming artificially, either half could be taken for a new swarm, on the plan of the old section straw hive, once so much in use in Germany.

In proof of the assertion, I refer to the patent above named, and from which I copy a few lines to show more fully that some of friend Heddon's devices are quite old.

"The vertical pieces, M M, are made wide enough to have the edges of the several frames touch each other;" and, "Between the sides of the case and the movable frames I insert a wedge-shaped piece of lath for the purpose of closing the crevices between the several frames;" and, "The hive consists of three or more equal sections, of which two form the brood-chamber, for the purpose above named."

Now here, friend Root, we have the several tiers, the closed-end brood-frame, held together by a wedge (equivalent to a screw), all in shape to alternate, reverse, or invert at pleasure, and all of which belongs to the public. E. KRETCHMER.

Coburg, Iowa, Feb. 13, 1886.

IMPORTED ITALIAN QUEENS AND THEIR PROGENY.

ALSO SOMETHING ABOUT FRIEND BENTON'S SUCCESS IN SHIPPING BY MAIL.

IN reading friend Doolittle's article on imported queens, or their daughters, in GLEANINGS for Feb. 15, I am aroused to speak just a word in their favor. My experience in bee-keeping is very small, and much less with imported stock; however, I like to speak once in a while, whether my few words are of any importance or not. In the fall of 1884 I wrote to Mr. Benton (at Munich, Germany) for sample workers of his Italian and Cyprian bees, and inclosed 10 cts. to pay postage on them. About a month later I received the bees in good shape; and on opening the cage I found a medium-sized Italian queen, rather dark in color, though bright and lively, after her 14-day journey. They were accompanied by a letter, stating that he feared the bees would worry themselves to death if shipped alone, so he picked the poorest-looking queen he had, and sent her with them. He said her progeny had not hatched, so he could not tell what her bees would be; but he said, if I thought her worth $1.00 to me I might send him the additional 90 cts., which I did at once. He said her mother was imported from Bologna, Italy.

I introduced her at once, and in less than twelve hours she was depositing eggs. This was about the 20th of September, so her bees did not have a chance to fly much. They were like her, rather dark, though all three-banded. I put them in the cellar the 18th of November, and took them out the 25th April. She was bright as a dollar. The bees were mostly old when put in, in consequence of which they were reduced to two frames of bees, both of which were partly filled with brood. I fed them nothing, nor gave them any additional brood, and from that time till the latter part of June I took from her 11 frames of brood, with all adhering bees, to help build up others that were just as strong when set out. They were strong enough by this time, so I divided them and made two good colonies in 10-frame hives.

The latter part of July I extracted from the artificial colony (after raising their own queen), 50 lbs. of fine honey. I weighed the hive early the next morning, and again the following morning, and found a gain of 11 lbs., and a one-story hive at that, This is my only experience with imported stock; but I think it speaks well for friend Benton's *cull*.

ELIAS FOX.

Hillsborough, Wis., Feb. 22, 1886.

CELLAR WINTERING OF BEES.

A DIALOGUE.

"GOOD morning, neighbor D. I called to see how the bees were wintering. I am losing some of mine."

"Am sorry you are losing bees, friend H. Mine seem to be wintering well, especially those in the bee-cellar. In fact, I never had bees appear so nice and quiet as they do this winter in the cellar."

"Should like to see them; but from what I read, written by some of the 'big lights,' I suppose you never go into your bee-cellar after the bees are put in until you do so to take them out in the spring."

"Oh! yes, I do. I go into it regularly once every two weeks, and oftener, if I think any thing needs doing in there. I suppose I am considered a heretic on this question; but be that as it may, I have every reason to believe that no scientific wintering of bees can be accomplished when no observations are taken, except when the bees are put in and taken out of the cellar. Bro. Ira Barber gives the temperature of his cellar as ranging from 60 to 90°, while by private letter he says he does not take a register of the temperature except when he puts them in and takes them out. These figures, therefore, are of necessity misleading; for all know that the commotion caused in moving bees would raise the temperature of the cellar much above the normal heat. I venture the assertion, that if Mr. Barber will take a daily register of the temperature of his cellar, as does Bro. L. C. Root, by letting a thermometer down through a hole in the floor, he will find that the temperature of his cellar is not much above that reported by other bee-men. But, come; if you wish to go into the cellar we will go."

"What! got three doors to go through to get in?"

"Yes; these three doors inclose two dead-air spaces, and it is a rare thing when any frost gets in this second space, where we will stand while I close the two outer doors and light a lamp. Now, before we open the other door I wish to say to you that you will be careful not to hit any of the hives, nor breathe in any way except through the nostrils; for the breath by way of the mouth in the cellar arouses the bees more than hitting the hives, both of which I desire to avoid."

"What is that low murmuring noise I hear?"

"That is the contented hum of the bees in their winter repose, and you can always know that bees are wintering well when 50 colonies make no louder noise than you now hear."

"But according to Clarke, of Canada, I thought that bees, when wintering well, were 'hibernating,' and gave no signs of life."

"Bees never hibernate as do ants, wasps, flies, etc.; and I can not indorse friend Clarke's word as applicable to bees. Quiescence would be much more appropriate, in my opinion, than hibernation."

"Hark! there is a bee flying. Do they fly out here in the dark?"

"Yes, that is only a bee ready to die with old age; and as instinct prompts the old bees to leave the hive when the temperature will permit, it is only obeying nature's law in flying out. See, here are quite a few bees on the floor, but not nearly as many as is the average of most winters. I often come in here in the dark, and listen for these old bees; and many times before this winter, from two to five would fly out while I was counting 100 slowly; but this winter scarcely more than one comes out while I count 200."

"What have you on the floor here? Sawdust?"

"Yes, every month I bring in about a bushel and a half of fine dry basswood sawdust, such as I make while sawing sections, and scatter it on the floor. This sawdust will absorb almost its bulk of moisture, so I keep it in here to keep all dry, sweet, and nice. Before I used this, the dead bees on the floor would mold and smell bad, and the combs near the bottom of the hive would also mold; but now all smells sweet and nice, and no mold appears."

"Here is your thermometer. I see it marks 44°. What is the extreme of temperature in here?"

"From 43 to 45° above zero. After the first few days when the bees are set in, then it is as high as 55 to 60°, but lowers to where you see it."

"What, doesn't a warm spell in winter, or a long cold spell, have any effect upon the temperature in here?"

"No: and a cellar that allowed of the outside temperature affecting to any extent that inside, I should consider faulty. There are two roofs and three feet of dry earth over this, which, with the three doors, keeps an even temperature. Now step up and look at these yellow fellows when I take off this sawdust cushion and roll back the quilt."

"Why, Doolittle, they are dead."

"No, I guess not."

"But they don't stir."

"I will breathe upon them."

"They are alive! that is a fact. Do they keep always thus quiet?"

"I have never seen them more uneasy this winter; but the year I used artificial heat, and lost so heavily, I could not lift a quilt like that without their boiling all over the tops of the frames."

"Where are your ventilators?"

"Here is the sub-earth ventilator, but it is shut off at the outer end and has been for the past three months, while the other ventilator is in the opposite end, and at the top. This also is shut down to a hole less than two inches in diameter, as I find that all the air the bees need to keep them in the best condition comes through the masonwork, doors, and earth covering. This is what some call no ventilation whatever; but you see the air is pure and good in here. Well, we will go now; but first notice that the bees are nearly if not quite as quiet now as they were when we entered a quarter of an hour ago. If our entering does not disturb them any, why should I not have the privilege of coming in here as often as I please? Good-morning. Come again when you wish to learn more of the bees."

G. M. DOOLITTLE.

Borodino, N. Y., March 1, 1886.

There, friend D., you have got your bee-cellar so you keep it just about the temperature of that deep cold well you told us about, and that is pretty near the temperature of old Mother Earth in your locality. I am somewhat surprised, however, that you are able to keep it so low with the ventilators shut off as you have them. It seems to me your bees are quite accommodating this winter. Ernest wishes me to say that the above is just to his notion, because it is so very plain and clear that even the juveniles will understand every word of it.

WORKING WITHOUT SEPARATORS, ETC.

ALSO A SUGGESTION IN REGARD TO GETTING LARGE YIELDS OF COMB HONEY, EVEN IF YOUR BEES DO SWARM.

THE following article was so lengthy as it came to us, that Ernest clipped off the last end of it, and it appeared on page 186 of last issue. As friend King did not feel satisfied with our mutilation of his production, the matter was referred to myself. After a careful examination, I decided there was so much value in the article, even though it were long, we give it here, and thus we have the first part last.

I do not use separators. With me they are an unnecessary trouble and expense. Last season I visited a neighbor's apiary,—found about a million little wooden separators with his surplus arrangements. He had some nice straight sections; so had I *without* separators. I think I can get more marketable honey without them. If I have an occasional thick or bulged one, I keep it to sell to my neighbors. I find but a few, however, and am often obliged to take from my nice smooth ones to supply the neighborhood demand. I *have* used separators, also wide frames with separators, but I do not care to change from my present system, which I have used long enough to know how it goes.

I use a Heddon case with a false section, or block, ¾ in. thick at one side. When filled and *glued*, I can easily remove this block, when the sections can be readily taken out.

My principal business is working for comb honey; and what I want is the best possible result and, to obtain this with as little work per colony as possible, consistent with good management. I am willing to *work*, and always find plenty to do; but I always aim to avoid any unnecessary manipulation. If it is desired to force all the honey from the brood-chamber at the commencement of the honey season, and fill the hive below with brood, I can usually accomplish this, practically, at one operation, which every bee-keeper must do at least once at swarming season; and if no swarm occurs, *this* is not necessary; for what good strong colony is there but will store an abundance of comb honey if no swarm be cast under ordinary circumstances?

But we were speaking of the probability of one swarm being cast per colony. One writer mentions that if the combs be reversed at the proper time, swarming will be allayed. What an idea of benefit is this! Who can tell, without almost daily examination, when this "proper time" is? Probably about once in fifty times, one would guess right, and nothing will so likely increase the desire to swarm, as reversing combs and increasing the amount of brood and bees. I believe in strong colonies and lots of bees, but I don't think it necessary to carry it to an excess; and it is a question with many prominent bee-keepers, if not more comb honey can be obtained from a given number of colonies, if they were not allowed to increase the capacity for brood-raising to more than half the capacity that would be reached by reversing frames, thus preventing swarming in nearly all cases, enough brood being hatched to keep the colony strong and in good working force. The surplus honey needed for brood-rearing, would thus be stored in the sections. It seems to me that some who have been advocating little manipulation of combs, have now taken a widely different stand, and are inventing plans which end in the excessive manipulation of combs, hives, etc., without any decided advantage. If a moderately shallow hive be used, there need be no difficulty at just the time required to practically fill all the frames with brood if desired, by the plan I use for the prevention of after-swarms, and to keep my working colonies in prime condition for storing comb honey every day of the season.

I have had many colonies in my yard this last season, which, during the height of the white-clover season, were literally filled below (10 frames) with brood, while they were carrying along nicely a couple of cases of sections; and I believe if I should wish, I could, in nineteen cases out of twenty, produce the same results, and, too, without the use of reversible frames. How many bee-keepers there are who are often heard to remark, "If I could only keep my bees from swarming," believing as they do, that any colony in good condition in the spring would store a satisfactory amount of honey during the early honey season if no swarm were to issue. A few bee-keepers claim that they can obtain as much comb honey from a new swarm hived on fdn., as they would from the old colony if no swarm had issued. I believe this to be far from customary, even with those who have advanced such statements, and that all such occurrences are but rare exceptions to the general rule. As it is natural for bees to commence swarming at the beginning of the honey season, such swarming may be expected, if not depended upon. In nearly all cases, colonies that send out first swarms about the commencement of the early honey season, have made more or less advancement on their sections, which must be suspended, unless the swarm (the new colony) will continue the work.

Now, what shall be done to keep up the work in the sections? A great many would return the swarm. I have done so, but I don't any more in the early part of the season. Every one knows how "strong," as we say, a new swarm will work. My plan is this: If a swarm issue, hive it on a *new* stand. At the time, or soon after, give them about ⅔ of the brood they have just left; fill up the body of the hive with frames of fdn., place the sections they have left, upon them, and you have them at work on the sections with even more zeal than they had before, and without any delay, and upon the old stand you have a nucleus "as is a nucleus," into which, after the first night, slip a virgin queen if possible, and it will be a strong colony amazingly quick, and ready for winter in good shape, and fall-honey surplus, too, if there be any. In this way all after-swarming is prevented, the number of colonies is doubled, or nearly so, and the original number of working colonies is kept strong, and hard at work, too, on the sections, every day, through the honey season.

In introducing queens, either laying or virgin, I do not consider it necessary or wise to leave the colony undisturbed more than a few hours after releasing the queen. If they are all right next day, I consider that enough; if they are rejected, they will be missing, and it is time we should know it. I have never lost one from opening the hive the next day, or soon after, and I have introduced hundreds of them. C. W. KING.

Kibbies, Mich., Feb. 10, 1886.

After reading the above, please turn to page 186 of last number for the rest of the article. —The plan of saving bulged combs for the home retail trade is an excellent idea; and for economy in packing away neatly, we can set them in the regular retail cases by putting empty sections between sections where the honey is bulged out very badly.—The plan of giving the brood-combs from the parent stock to a new swarm has been a good deal practiced; but friend Doolittle and others object, as it often causes continued swarming. When your bees get a swarming mania, very likely this may be a trouble. If they have not a queen to swarm out with, they will often swarm as soon as they can get one hatched.

MRS. HARRISON TELLS US HOW THEY WINTER THEIR BEES.

CELLAR WINTERING COMPARED WITH CHAFF PACKING.

MR. EDITOR.—Your chaff hives may be the very best for wintering bees, and far ahead of cellar wintering; but, what are we to do who have not got them and are not able to procure them? We are wintering forty colonies in the cellar, and, as far as I can judge, they are as bright and as healthy as in June. The cellar is paved with brick, and I occasionally sweep up the few dead bees, and the air is sweet and pure. Once, during a very cold spell, the thermometer went down to 38°; but most of the time it kept at the neighborhood of 45°. The bees were put in the 23d of December, after enjoying a fly for several days.

The bee-cellar is partitioned off from the main one, and has a sub-earth ventilator. As far as I am able to judge, the ventilator does not lower the temperature, if kept open during severe weather, and there appear to be counter-currents through it. There is a window, hung on hinges, but there has been no occasion to open it as yet. Since the introduction of the sub-earth ventilator, the air in the main cellar is much purer than formerly, and no mold accumulates.

As to "lugging hives in and out," there are plenty of men on the street-corners glad to do it for a consideration, and two men could carry in one hundred in half a day. Longfellow says something like this: "Take whatever lieth near thee, and work from it thy work of art." I could not command chaff hives, but I had the cellar, and a few dollars fixed it up for bees; and some men, glad to earn a few pounds of honey, carried the bees in.

About as many colonies are wintering on their summer stands, protected in four different ways. I had some barrels not in use; some were oil-barrels, others apple and pork barrels. The bees had on Hill devices, covered with new muslin, which was fastened down to the top of the hive by running a hot smoothing-iron around to melt the propolis, so no bees could come up; then two thicknesses of woolen cloth and wire netting over this, which was kept firmly in place by nailing on little cleats of wood. When thus prepared, and the bees fastened in in front, they were ready to barrel. Into the bottom of this was poured a quantity of chaff, and the hive (an eight-frame Langstroth) dropped in. All around the hive, chaff was packed very closely —bottom, top, and sides, and then turned down upon its former stand. Colonies in the barrels appear to carry out fewer bees than the others, and during warm days they play as in summer.

I have one hive called Cyula Linswik, as it is fixed as nearly as possible as Mr. Hutchinson described her manner of wintering. A number of hives are placed against the east side of our house, and packed between and around them with leaves, chaff cushions on top, and the whole covered with boards to keep off wet. A few hives are standing singly, with four thicknesses of newspapers above the muslin, and the cap shut down over paper, and chaff cushions above—one without paper. I expect the barrel hives to come out ahead; if so, it will prove the value of chaff hives. As the bees upon their summer stands have access to water frequently, I shall put wet cotton rags in the porticos of those in the cellar, so that they can help themselves if they wish to. Bees are now upon the wing. MRS. L. HARRISON.

Peoria, Ill., Feb. 23, 1886.

By all means, winter the bees in the cellar when you are situated so it will be the handiest and cheapest, Mrs. H.—In regard to cheap help, there are men standing around here in Medina as well as in Peoria; but my experience is, that it would be about as much trouble to teach them to carry the hives into the cellar, and set them down properly, as to employ expensive help for the purpose; and sooner or later these same men who have not any thing to do, usually want about as big pay as anybody.—Very likely your barrel arrangements for packing outdoors will answer; but is it not a great deal more trouble, and, in the end, expense, than to have chaff hives that are always ready for both winter and summer?

ANOTHER DANGER AHEAD OF US.

A THREATENED INCREASE OF POSTAGE ON FOURTH-CLASS MATTER.

OUR readers may not all be aware there is a movement on foot to increase the postage on seeds, merchandise, etc., although it is now four times what it is in Canada; that is, we pay one cent an ounce, while the Canadians pay one cent for four ounces. I have written to our Representative from this district, and I have also written to Prof. Cook, to ask his help. Here is what he advises.

Dear Friend Root:—Indeed this postage matter is a subject of tremendous importance. We can each only appeal to our Congressmen; and when we can, write up the matter for papers, and send papers to our Representatives and Senators. Why not you ask all readers of GLEANINGS to appeal to their Congressmen? I don't think the bill can pass; but there is danger. A. J. COOK.

Agricultural College, Lansing, Mich., Mar. 2, 1886.

Later:—The bill has failed.

CHAPTER XI.

The laborer is worthy of his hire.—LUKE 10:7.

One of the most interesting things regarding any kind of work is the point where the cash comes in. When you set children at work, they usually like to see the cash come in pretty soon. A great many of them would like their pay every night, and some of them, indeed, think it a hard thing to wait until night comes. Well, we children of an older growth are a good deal that way. We do not like to work a great while without seeing some of the dollars and cents. Years ago, when I earned 25 cents by being at the head of the spelling-class more than any other pupil in the old schoolhouse, I debated quite a time as to how I should invest the 25 cents. I finally decided on launching out into the poultry business. So I invested the whole of my 25 cents in poultry. I talked the matter over with my mother, and got her opinion and experience. I suggested, that if I invested in poultry, I should get returns for my investment right away. "Why, mother," said I, "if I buy two good hens, they will lay two eggs the very next day, will they not?" She thought likely they would; so I purchased two old biddies with my 25 cents, and rejoiced in being the possessor of two large white eggs, almost before I had got my poultry yard and house ready for the occupants. I swapped my eggs to my mother for corn and other necessary feed. Like a wise and good mother, she taught me to sell my produce at a fair market price, and pay for the feed. Of course, I soon learned, as has many another juvenile poultry-keeper, that it does not necessarily follow that I should have two eggs every day in the year, simply because I was the possessor of two good hens. I think I figured out that, with good care, I could depend on *one* egg a day for *three* hens. This was over thirty years ago. I do not know how much advance has been made in poultry since that time. Probably some of the non-sitters will do better. But I think an egg each day in the year, for three hens, is a pretty fair average, even now. My juvenile figures demonstrated that, as a rule, one egg a day, judiciously invested, would furnish food for *five* hens, so there is not, or, at least, there was not then, any very dazzling profits in the poultry business, where one has to buy the feed and sell the eggs at the market price, to be consumed for food. Of course, if we are enabled to sell our eggs for breeding purposes, at one or two dollars a dozen, it puts quite a different shade on the business; and, by the way, we are to make our money by raising the best, and *the very best*, of every thing. The world is full of people who have plenty of money, and who are willing to part with their money for nice things—*nice* products, for instance, but who won't pay out their money at all, unless they can see something a little above the general average.

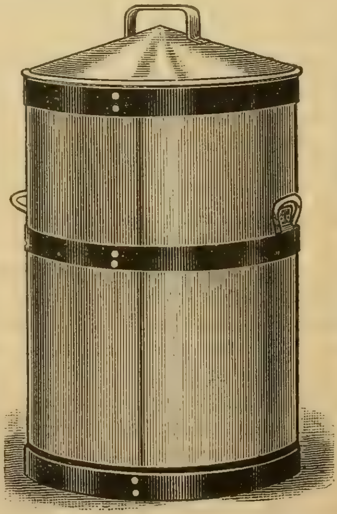
Now, this same idea is to apply to our plants. A little money is *very* convenient to have when you are starting out in any business; and it seems to go a great deal further, and do a great deal more good, when it comes as a result of that business. The friends have often accused me of having more of a liking for small bee-keepers than I have for large ones. They say I publish reports from some A B C scholar who has only one hive of bees, and correspondingly little experience, when I would entirely pass by a finely written article from one who counts his colonies by the hundreds, and his honey by the ton. I do not believe it is quite as bad as that, but yet I do not know but I ought to plead guilty, to a certain extent. I do love to see people start in business, especially, where they start in a healthy, self-sustaining way. I like to see a boy raising nice heads of lettuce; and when I see him on the market with a basketful, swapping these heads of lettuce for nickels, why, I just love that boy. I love the man or woman who buys his product, too, and I love the basket of lettuce. The whole transaction is a healthy, honest one. The boy is putting his shoulder to the wheel, and doing his part in the general economy of the world. He is a man in business on a small scale; and if he is thrifty and prudent with his little business, he will be so with a larger one. Why, we have God's promise for this very thing—"Thou hast been faithful over few things, I will make thee ruler over many things."

I suppose many of the friends have at

this date (it is toward the middle of March that I am writing) boxes full of beautiful little plants peeping forth from their mossy coverings, and asking, as well as they can ask, with their bright green leaves, to have more room and sunshine. How shall we get it? Windows warmed by stoves, greenhouses, cold-frames, and hot-beds, are all comparatively expensive. Very likely you have every inch of space occupied; may be you have boxes of plants, such as I have described, standing across the paths, so that when you go through your greenhouse you have to stoop down and crawl under, something as we did at Mammoth Cave, when we went through the passage called "Fat Man's Misery." Very likely you have boxes perched up in every possible shape, to get even a small share of sunlight that comes through every day or two. Well, what next? In most localities you can, by the middle of March, begin to make garden to some extent out of doors; that is, as soon as the frost is out of the ground you can put out hardy plants and sow hardy seeds. We want to begin to get rid of the expense of glass sash just as fast as possible, and yet we do not want to take risks, and have our plants either frozen outright, or greatly injured by being frosted. Let us work orderly and soberly and *surely*.

Where shall we have the garden, and how shall we fix it? Well, I would commence making garden in some protected spot such as I have mentioned for cold frames or hot-beds. If you can find a corner close up to some building, so that there is a protection on the north side and another on the west, to perfectly cut off north and west winds, you are all right. If the frost won't let you dig, clear off the ground so as to catch every bit of sunshine; and as fast as the sun thaws off a half-inch, scrape it off and let the sun get at the next half-inch, and so on. Pile these scrapings in a heap loosely, mixed with manure, and they won't freeze very much. Cover your ground at night with straw or old boards, or, better still, coarse manure. When you get down through the frost, dig your ground up and break it up fine to the depth of two feet or more, mixing it with manure, the best you can get.

Probably one of the first things you will get money from will be plants for early lettuce, cabbages, cauliflower, celery, onions, cress, etc. Now, you can attract visitors, and attract custom, by having this early garden neat and orderly. Weeding among these little plants, and pulling them to tie in bunches, is laborious and back-breaking work, and I think it pays to make sunken walks, or paths, something as we do in a greenhouse, so as to raise the surface of your beds, say two feet high. The way we do it is to get some cheap 2 x 4 scantling; drive stakes in the ground, saw them off square, and nail a scantling on top; then get some old boards, drive them into the ground a little, and nail them against the sides of the scantling. Now shovel the dirt out of the paths, and throw it over in the center, mixed with manure. If there is a peat swamp near by (and you can almost always find one), draw peat and mix it with the soil. Peat will not only make the ground light, but its dark color will attract and hold the heat-giving rays of the sun, and will make your ground thaw out a good deal quicker than it otherwise would. It also prevents crusting. Ashes are also an excellent thing. Gregory, in his new book on fertilizers, calls hard-wood ashes worth from 30 to 40 cents a bushel. And I notice that most of the agricultural writers put them as high. In very many localities you can buy great quantities for 10 cents a bushel, if you pick them up from house to house, where they ordinarily throw them away. Get a tinsmith to make you some cheap tin cans something like the one shown in the cut below.



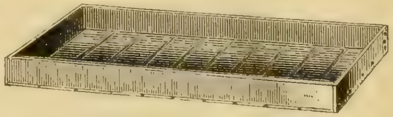
A CAN FOR SAVING ASHES.

It is true, a barrel will answer; but it is unsafe to store ashes in barrels, as has been repeatedly demonstrated. A tin can will last a lifetime, if properly cared for, and it is quite safe, light to handle, and easy to load up. Almost any tinsmith can make you a can holding about two barrels, for $1.50. He may have some damaged or rusty tin that he can work into it. For a dollar more you can get one of galvanized iron, with a cover to it, like the one in the picture. Leave these cans at the houses where they burn hard wood, and you will have your ashes all in good shape whenever you call for them. A few ashes raked into the surface when you put out your plants, or sow your seeds, will do almost as much good as guano or any kind of phosphate.

CAUTION IN REGARD TO USING ASHES.

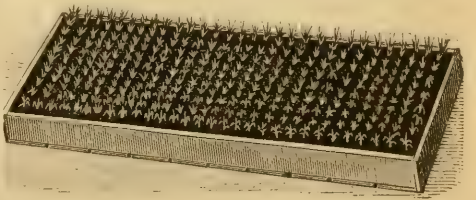
These, as well as guano and almost all other fertilizers, remember, must be applied in homeopathic doses, and at the same time be thoroughly mixed in with the soil. Last fall, when they were putting lettuce-plants in the central bed in our greenhouse, it occurred to me that a coat of ashes would be a good thing to stir in with the peat and earth put on top of the stable manure. Accordingly I went over to the house and got perhaps half a bushel. I poured the ashes down in a certain spot, and then tried to spread them all over the bed. As a matter of course, there were more ashes left where the half-bushel was first poured down than on the other portions where I raked it over. They should have been sifted over evenly with a sieve, and then raked in, say at least two inches deep. On a large scale, the best implement for the purpose I have ever seen or heard of is Kemp & Burpees' manure-spreader. Well, I raked the ashes in until I thought they were mixed enough. Then we set out our good strong lettuce-plants. They started nicely, except where that one-half bushel was poured down. The boys wanted to dig these up, when we found them wilted, but I told them to let them be, as I wanted to see just how too much ashes would act. Well, a great part of the plants died; but here and there one remained that was able to stand the dose; and by the first of February these few began to take hold and grow, and, oh how they did grow! It is only once in a while that I get a luxuriance of growth that satisfies me; but these plants satisfied me in every respect. The leaves had a rich, bright, dark-green look, and they unfolded and stretched out at such a rate that there was a big change visible each night and morning. They made enormous heads of lettuce in just a few days, when they got a going. Well, this satisfied me that ashes may be applied at the rate of half a bushel to every eight feet square, without doing harm, if thoroughly raked in and stirred up with the soil; and this fertilizer has one advantage over every other. It will never evaporate nor get lost. If the first crop does not use it all, the next will take what is left. Now, friends, save the ashes.

I told you what kind of beds we were making for raising plants. Now, much depends on starting right, and in having a system with this kind of work; therefore it behooves you to decide on a regular width for these raised plant-beds. I would have the scantling that runs along each side just far enough apart for common 3 x 6 sash to catch on lengthwise. Have one of the scantling a little lower than the other, so as to shed rain. Three or four inches will be enough. We want the beds made so that we can set in our shallow boxes, heretofore described, or so you can put the plants right into the earth, either way. For the first time in transplanting, we use shallower boxes, and made of lighter stuff, than those figured in Chapter IX. The kind we are using now for transplanting celery are 3 ft. long and 16 inches wide, outside. In order to get strength with lightness, we make them as in the cut below.



TRANSPLANTING-BOXES FOR SEEDLINGS.

To give drainage and strength, we have the bottom made of slats only three or four inches wide, and only ¼ inch thick. They are nailed on crosswise, as you will notice. Such light stuff would not be strong enough if put on lengthwise of the box. The sides of the box are 1½ x ½ inch. These are very easy to carry about, and answer just as well for small plants. From one of these boxes, the seeds of which were sown on the plan given at the close of Chapter VIII., we got 7500 plants. The plants were taken up, and set in larger boxes filled with soil, by means of the frame of poultry-netting shown in Chapter IX., so as to present about the appearance shown below.



A BOX OF WHITE-PLUME CELERY-PLANTS AS IT APPEARS WHEN FIRST TRANSPLANTED.

You will observe that there are 10 rows of plants, and 30 plants in a row, so it took 25 boxes, with 300 plants to a box, to contain just what grew in one single seed-box. The engraver has done his job pretty well; but nothing can equal, to my mind, the sight of these 25 boxes when the sun comes through the fleecy clouds during some March day, and lights them up as they stand south of the factory in their respective beds. Of course, we put sash over them at night when we have freezing weather. Do you object because this costs money? The boxes cost us about 10 cts. apiece, and I think they could be furnished without any trouble for 8 cts. apiece, in the flat; and it is just fun to nail them up on stormy days or winter evenings. Each 3 x 6-ft. sash covers 4 of these boxes, giving a little room to spare, so as to handle them easily. Do you object to this transplanting as a great deal of trouble? With the poultry-netting frame, almost any boy or girl whom you could pick up will tease to do the work when once shown how, and I think the transplanting can be done in almost any neighborhood for 10 cts. a thousand. You can let the plants grow in these boxes until they make a perfect mat. If it is too early to set them out, cut off the tops with a pair of shears, and in a few days they will be all out green again. The clipping-off makes a stout, thrifty, strong root. When you want to plant them outdoors, carefully slip the box off from this mat, and cut it up into little squares with a long butcher-knife, as I have before mentioned. If all the neighbors who see them don't want these little plants, with their strong mass of roots, your community is different from ours. What do you suppose the 7500 will bring during nice showery weather in May or June? They ought to bring readily $2.50 a thousand; or if sold in hundreds, 40 cts. a hundred. You will notice by the prices in the seed-catalogues, that they charge a great deal more—some of them going as high as $10.00 a thousand for good strong celery-plants early in the season. Suppose, however, you do not sell the plants, but set them on good soil. At 5 cts. per stalk (and good celery rarely retails for less than this) your crop would bring you $375. And this is all the proceeds of one little box of seeds.

The same thing may be done with cabbage-plants, and, to a certain extent, with lettuce-plants. We sold a barrel of heads of lettuce last week at 25 cts. per lb., giving us about $8.00 for what grew on perhaps 8 feet square of ground in the greenhouse; so the first crop from our greenhouse brought us 12½ cts. per square foot of ground. Well, when the lettuce was thinned out we put radishes between the rows, and the radishes are now selling for quite a little sum. After the lettuce was *all* out, tomato-plants were put between the radishes, and they are now making good growth, and will have all the ground as soon as they can use it. The ground in these beds was made perhaps one-fourth part stable manure. Guano was afterward dug in between the rows. In fact, it was manured up to the highest point, in order to have it bear continuous cropping; that is, we have the ground constantly full of roots, and the surface of the ground almost constantly covered with foliage of some kind. Instead of taking the crop entirely off, we take out every other row, and sometimes every other plant, and then some other plant goes right in between. You see, brains are needed in this work; and who does not feel happy to have his brains all employed in something useful? Sometimes people employ their brains and their waking moments in thinking of a quarrel with a neighbor. What a contrast! Well, I have told you what can be done with a little bit of ground in the way of lettuce and celery. When these get so they can go outdoors, we want to give the space under the glass to tomato-plants, and others of a tender nature. We are putting tomatoes now in the place of lettuce and radishes, and shall soon have our greenhouse almost entirely filled with tomatoes, while these other things grow outdoors. Now, in regard to what may be done with tomatoes, pushed along in advance of the season, I will let friend A. N. Cole, from his "Home on the Hillside," speak. Perhaps I should explain, before giving his letter, that our beds outdoors are warmed by letting the exhaust steam, after it has warmed our factory, go into those stone reservoirs, just above the water-line. The steam warms up the stones and the water, and the ground for several feet each side of these reservoirs, so much that it seldom freezes, unless the temperature goes pretty nearly to zero; and when it does freeze it is only a little crust over the top, which thaws out very quickly. With the aid of steam, it forms a veritable hot-bed, Well, I had corresponded with friend Cole in regard to this, and he alludes to it in the following letter:

RAISING TOMATOES BY THE NEW AGRICULTURE.

Dear Brother Root:—I confess to uneasiness in regard to tomato-plants. Mrs. Cole, by great painstaking, and with much of labor, aided by her husband, succeeded in setting upon our trenches, about the middle of May, the first of our plants in blossom, grown to a size in the bay-window, and "soul carting" the boxes day after day for two months on every warm day till acclimated, and "harvested" our first large, ripe tomato one week later than our great strawberry show; to wit, July 13th. At this date, tomatoes had found their way to our town from Charleston—pale, sickly-looking, and soft—*unfit, in fact,* for use, and yet finding ready sale at ten cents per pound, retail, costing our dealers 8 cents by the crate. Those from the Carolinas, as well as my own, were of the "Early Cluster" variety, earlier by two weeks than any other, and though least valuable in fact, nevertheless sold readily in all of the markets of our State, holding up to prices from eight to ten cents per pound at retail to about August 1st.

I think I am safe in saying, that millions of pounds of the Southern tomatoes were sold in this State alone during the last half of July. Here is where the oil cloth sold by Henderson will come in to good advantage. A skeleton frame of wood, consisting of stakes, open at top in the form of a clothespin, into which connecting-bars may be dropped, and pinned at their ends to prevent spreading, would give you a row of tomatoes ripening by slightest surface protection with the Henderson oil cloth in the months of May and June. You might need sash during February, but these could be above your skeleton frame; and so soon as the tomatoes are where cloth protection will do the work, the sash can be used elsewhere.

Perhaps the better way would be to protect by sash, exposing on every sunny day, till the blizzards have passed, and, when safe to do so, remove the sash and substitute the skeleton frame and oil cloth till all danger of frost is passed.

What I especially covet is about ten or twelve, or possibly a score, of "Early Cluster" plants, and a corresponding number of other varieties, to be supplied me as far advanced as possible, that I may set early, protect, and secure tomatoes as early as it is possible to realize ripe ones in this latitude.

I have had so much to do, and my resources have been so taxed in all ways, that your beginning has been a profound satisfaction. I propose to have all ready in the fall, to push the hot-water feature myself next winter. In the meantime, *your* success is something I am watching with all-absorbing interest. I feel very sure—yea, morally certain—that, if you will only buy good firm cotton cloth and dip it in oil, thereby making your own oil cloth, the protection will be found complete. Do not fail to provide me with the tomato and squash plants. I should like, also, a few very early and well-rooted cabbage-plants. Write me as often as you can.

Your friend, A. N. COLE.

HOME ON THE HILLSIDE,
Wellsville, N. Y., March 9, 1886.

I have given place to friend Cole's letter, because it shows us what may be done with large, strong, early tomato-plants. We have just sold off the crop of lettuce from our central bed in the greenhouse, where I got on too many ashes, and we are to-day, March 12, filling the bed with tomato-plants of the "Early Cluster" variety, having their second pair of leaves well begun. We are setting the plants out with the poultry-netting frame, so as to have them come about 3 inches apart in the row, and rows 5 inches apart, for better opportunities for cultivation. The plants will stand here until they begin to crowd so much they demand extra room, and then we will remove them to the ground over the reservoirs, covering them as friend Cole suggests. We have had a good opportunity of testing the oil cloth furnished by Peter Henderson, but it is altogether too light to in any measure take the place of glass sash. I have, however, found an article that works splendidly, and gives perhaps as much protection as glass, but it does not give as much sunlight in the daytime. This material is strong cotton cloth, a grade that we term "Indian Head." It retails in the stores for about 7 or 8 cts. per yard. When we needed the glass sash for our newly transplanted celery and cabbage plants, the sash were taken from the cold frame as shown in Chapter X.; and in their place we substituted cotton cloth, as mentioned above. First we were greatly troubled by the wind, and I found it necessary to fasten a long strip of wood to the edge of the cloth on each side. The cloth was attached to the strip of wood securely by nailing a strip $\frac{3}{8}$ x $\frac{7}{8}$ along its whole length, with the cloth between the two pieces. Some similar strips were screwed up and down each gable end. We now had it secure, but the frost went right through it when the thermometer was down to 10°. It didn't answer in the place of glass at all. Finally I instructed our painter to give it a coat of boiled linseed oil. It took several days for this to dry, but the oil has filled the pores in the cloth so that it not only stops the wind and air, but it holds water; and down by the eaves we sometimes after a rain find a couple of pails of water where the cloth has sagged between the rafters. It now keeps out the frost about as well as glass; but we find it necessary to bank coarse manure along the sticks that hold the lower edge of the cloth. You will see, by turning to Chapter X., that this cold frame is 23½ feet long. Well, we found at the lumber-yard some long narrow boards, this length, perhaps 6 in. wide, to hold the edges of the cloth. Suppose, now, after a cold freezing night, we have a warm sunny day, and by 10 o'clock the plants would be better without any covering at all. The course manure is pushed from the stick on the south side, and a man at each end will readily roll up this oil-cloth covering, and it is all out of the way in a minute or two. The frame may be covered and uncovered about as quickly as you would take off two of the glass sash. The expense of the cloth for this whole cold frame was only about $2.25. Two gallons and a half of oil and three hours' time, would make about $2.00 more, making about $4.25; or say $5.00 for sticks to roll it on, and all, while the 14 sash used to cover this same cold frame would be worth $25.00 or $30.00. I do not know how long this oil cloth will last; but it seems soft and pliable, and with care will doubtless last a great many years. Such a sheet is very valuable, many times, for thrashing grain or seeds. It is 4 yards wide and 8 yards long. Where we wish to get as much heat as possible from the sun's rays, I presume glass would be considerably better. But the air gets very hot through the oil cloth if the gable ends are not open promptly as soon as the sun has been out a little time. Another advantage in using cloth in place of glass is, that the heavy expense of breakage is avoided. We find it almost impossible to handle sash without breaking them more or less. I have learned this pretty well: That it is never safe to set up sash on end or on edge. When you wish to lay them down, put them down flat. Unless you do, the wind may spring up unexpectedly, and flop them over; lay them down one upon another, so no wind can get under any edge or side, and they are safe. In Jersey City I noticed the sash were piled up at each end of the beds, one on top of another, so as to make a square true pile. Sash is oftentimes handled more than is really necessary. When the days are not very warm, the sash may be tilted or moved to one side, so as to let the hot air escape from underneath, without taking them entirely off. It is, however, dangerous to take risks in leaving the sash off when appearances indicate at night that there will be no freeze. Almost every season we have lost more or less plants by a sudden change during the night, when we did not expect it. Bear in mind, we are to make our money by having all sorts of garden stuff in advance of the market and everybody else, and it does not pay to take risks. We want to make a sure thing of the operation.

CHAPTER XII.

But when thou art bidden to a wedding, go and sit down in the lowest room; that when he that bade thee cometh, he may say unto thee, Friend, go up higher.—LUKE 14: 10.

SELLING YOUR PRODUCTS.

As soon as you have any thing fit for sale, it must be sold; and I am not sure but it requires more brains, more energy, and more perseverance, to sell stuff at a fair price, after you get it, than to raise it in the first place. Now, don't say you haven't any faculty for selling such produce. If you want to build up a business, you must oblige yourself to learn the trade of selling things; and it seems to me that the first and greatest essential to success is that you commence with love to God and love to your fellow-men. These pages are not written to people who are well to do in the world, but for those who are poor and needy. If you have plenty of business of your own, remember that, although these pages may interest you, they were not written for you. They were written for the man or woman who is out of work. And another thing, if you have any *false* ideas in your head in regard to respectability in earning an honest living, they must be gotten rid of.

When you get a lot of nice lettuce ready for the market, and there is no demand for it, you must *make* a demand. When the plants begin to crowd, take out every other row, and finally every other head; and if you have more than you want to plant somewhere else, or if they are too large for transplanting, you must sell them. With a sharp knife, cut them off just at the surface of the ground. Pull off the faded and untidy leaves, and rinse the others with clean water. If the heads weigh about a quarter of a pound each, they are all right to be sold for a nickel apiece; or if it is early in the season, say February, or if it is where there is a good market, heads weighing two ounces will often bring a nickel. If the plants are so crowded as to be small, tie them in little bunches to make two or four ounces, as the case may be. Put them in a neat clean basket, and start out among your neighbors to build up a trade. Will some one say, "I wonder if you think that *I* am going about from house to house, to peddle lettuce, like some old market-woman?" My friend, I do expect you are going to do just that; that is, if you get help from these pages. See the text at the head of this chapter. If you are already in business, and have got started, and have a horse and wagon, all right; but I am considering now those who have nothing to do. You want a nice clean basket, and you want your bunches of lettuce tied up with some neat-looking string. Choose some color that does not soil easily. Wash your face and comb your hair; and may be you had better put on some clean shoes and clean clothes every time you go out to sell goods. A gardener is often necessarily pretty well covered with mud and dirt. When he sells stuff he must go into people's houses, therefore he wants to look reasonably becoming. Be civil and courteous, kind and neighborly, but don't waste time in useless gossip. Let your friends see by your movements that you have lots of business; and in this case I don't think it will be amiss in God's sight if you move about as if you *had* lots of business, even though you *haven't*. If you get into the habit of moving around spry, it won't be very long before there will be abundant need of economizing the minutes. Let your stuff do the talking as much as can be. Let everybody see what you have on hand, and tell them it is only a nickel. If it is muddy weather, be careful how you track mud on the clean steps or porches, or into the house. Work hard for the good of the people whom you meet, and let your face show by its expression, love to God and love to your fellow-men. Some radishes, white and red, tied up in bunches and put with the lettuce, will help to make your basket very attractive. Get out in the morning before breakfast with these things, if you can. If you can not get clear around, the next best time is before dinner. When the weather prevents your making your regular trip before noon, get around in the afternoon as quickly as possible. While you have a proper regard for your health, don't be too ready to give up on account of the weather. "He that observeth the wind shall not sow; and he that regardeth the clouds shall not reap." If you are going to be a successful gardener, you will soon learn to love to work out in the rain, if it does not rain too hard. Don't be troubled if sales are slow and small to start with. Do your duty, and trust God for the result. Many of our most wealthy men learned the secret of success in business in humbler callings than selling garden stuff. As soon as you can get some nice onions in bunches, they will sell among a certain class of people.

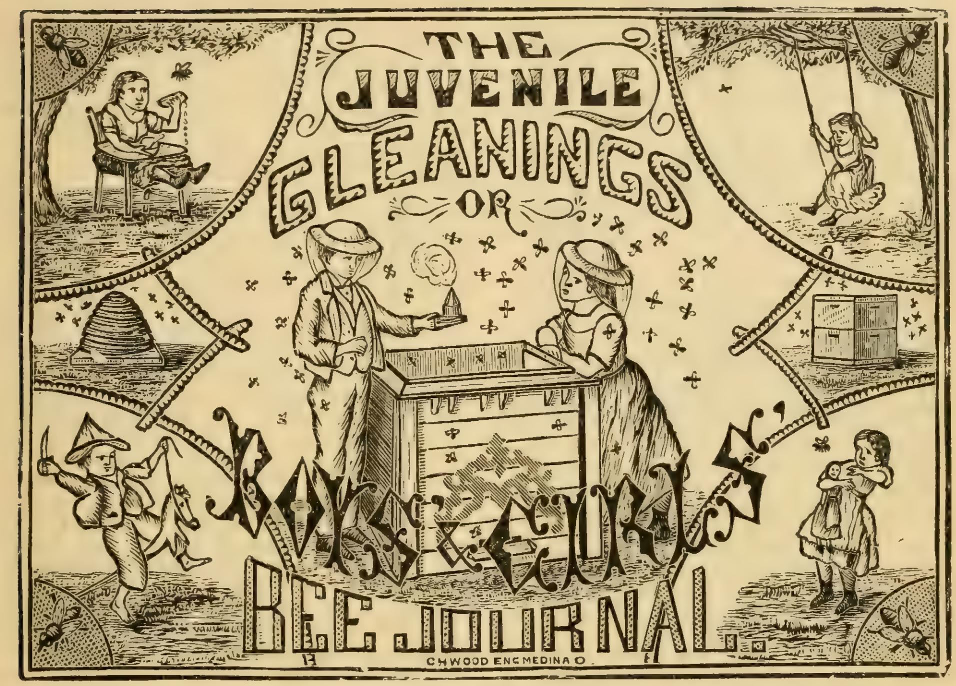
Don't make a mistake, and sell your stuff too cheap. Last fall, when our first yellow rutabaga turnips began to be fit to use, we started them at 25 cts. a peck, which, you know, is $1.00 a bushel. Well, the people got so much in the habit of paying that price for them, that we sold almost our whole product at a dollar a bushel. They were real nice, however, and that was the secret of it. Just as we were selling the last of them, farmers began to bring them to town, and sold them at 25 or 30 cts. a bushel. Now, had we commenced to offer them at 10 cts., instead of 25 cts. per peck, they would not have sold much faster, nor would people have been much better satisfied, probably. When you have secured a crop in advance of the season, don't be afraid to ask what it is worth, or what it will bring. Friend Cole speaks of 10 cts. per lb. for early tomatoes. If you can sell all you have raised, at 10 cts. per lb., that is positive proof that they are *worth* 10 cts. per lb. The products of the soil are always worth what they will bring. Strawberries are now quoted at $6.00 a quart in New York; and if there are people in that city who are willing to pay that price, it is right for the man who raised them to get it. If it is too high, let somebody else compete with him, and bring the price down. The world is full of people who are watching for a good margin on any thing. If somebody else is selling garden stuff besides yourself, by all means have your relations with him of a friendly nature. Divide the town, if you choose; but whatever you do, don't cut against each other, and thus cut down prices. If there is not room enough for two, talk it over, and let one buy the other out; or let one take one line of goods, and the other one, another. Don't quarrel; and don't, under any circumstances, hurt each other's trade. When your trade increases sufficiently, have two baskets made so as to hold as much as possible, and so you can take one in each hand. If something like the old-fashioned neckyoke, with which our fathers used to carry water or maple sap will be a convenience, don't be ashamed to make use of it. It is honest and respectable to bear burdens. By no means cultivate oddity or eccentricity, but choose such things as are real helps to you in your business; and if people do smile when you commence work, they will soon get used to it when they find you are bent on a regular, steady business, year in and year out. Nothing helps a man like sticking to his calling, as if he meant everybody to understand he meant it to be a life purpose with him. Meet your customers regularly, if possible, and in regular order. When the weather is suitable, a light wheelbarrow will be quite a help. Get up with the sun; work every hour in the day; and when you can not see to work outdoors, read the various periodicals devoted to your line of industry. Study books on gardening, which are now to be had by the score.

Pay as you go, and encourage your customers by every possible means in paying cash down. Always keep change in your pockets—enough to make change rapidly.

A great many people waste time and make blunders because they do not use the established plans of doing business. As an illustration: Suppose somebody takes a bunch of radishes and a bunch of lettuce, and gives you a half-dollar. Lay down the vegetables with one hand while you scoop the change from your pocket with the other hand. Then count this way: Lay the goods in the pan or on the table, or such place as is most convenient, counting as you drop them, "10 cts." Then take a dime from your handful of change and lay that beside them and call it "20 cts." Now put in a nickel, and say "25 cts.;" then put in a quarter, and say "50 cts.," counting out loud. You have the lady's half-dollar, and she has *her* 50 cts. in *goods* and *change* on the table or in the pan. You see, there is no subtracting by this method—it is just addition. She gave you a half-dollar, and you gave her half a dollar back, the vegetables making 10 cts. of her half-dollar. Make change this way all along, count out loud, then tell your customer to please see if it is right. Make everybody you deal with count after you, and express themselves satisfied; if you don't, you will have misunderstandings, contradictions, delays, and perplexities. The time-clerk in our establishment, when she pays the hands Saturday afternoon, has positive instructions to insist that every man count his money. Sometimes they grab it and push it in their pockets, all wadded up. She tells them her instructions are that every hand must count the money, and see if it is right. Two or three times they have neglected my instructions. For instance, a young man who had been recently employed, came to me saying that the time-clerk gave him a dollar too little, and that she refused to make it good. She declared she gave him the dollar, and he counted it, and he said it was all right. He admitted this, but said he made a mistake when he counted the first time. After arguing the matter some, I directed that the dollar should be given him, to keep peace in the family. How do you suppose it turned out? When the room where he worked was swept out, the paper dollar was found in the shavings. The time occupied by the controversy and by different hands stopping to listen to the argument, and to hear each one's story about it, cost me, perhaps, something near the amount in question. The time-clerk was an old hand at the business, and was right. And it will generally be found so. The one who is familiar with his routine of business is not so apt to make mistakes as one who does not handle money very often. The largest amount of work can be accomplished in a day if you can do it so surely and accurately that you won't be hindered by accidents and misunderstandings. Have your wits all about you, and do every thing as if your life depended upon being accurate and quick. If you are a sleepy individual—one who is in the habit of sitting down in the sunshine, and yawning, and telling stories, and gossiping in the middle of the day, I *can not help you.* You will probably be poor all the days of your life, and unhappy besides. Why, it sometimes seems to me *awful* to see great stout men sitting still, or lounging around with their hands in their pockets, during these bright spring days.

Now, then, take a low seat and work hard till your fellow-men bid you sit up higher. Astonish your customers by the beautiful heads of lettuce—by strong thrifty plants of celery and cabbage—so strong that almost anybody can see that each one is sure for a crop, and have some great thrifty handsome tomato-plants ready just at the time when everybody will be wanting them. A good strong plant, well rooted, ought to be worth a nickel, giving your customers a pot to carry it in. The same general rules will apply to every thing you raise on your ground; and when you become an expert in producing nice plants in small beds, you can extend the same process to acres, working slowly and carefully, and increasing your area only so fast as you can do it and do your work well, according to the spirit of the text at the head of this chapter.

To be continued April 15, 1886.



He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

Thou shalt neither vex a stranger, nor oppress him; for ye were strangers in the land of Egypt. —Ex. 22:21.

ONE day while I was sitting at my desk reading letters, I think it was about the middle of February, a stranger came up to me and asked for work. Request has been made so many times during this past winter, that I have got into the habit of being perhaps a little short and a little positive in telling them I had no need of any more help. This man bore very plain evidences of belonging to the class called "tramps;" and one's first impressions were that he was an intemperate man. His clothes were ragged, and he was a pitiful-looking object. After I had told him positively that there was no possible chance, and that old hands had been waiting all winter for a place, he started off with a dejected look that touched my heart. He was quick and keen, however, for he glanced back, and, seeing that my eye was on him he turned around and approached again.

"Mr. Root, could you not give me some kind of work to do, to pay for some sort of an old coat? My coat is very ragged, as you see, and I should be very glad to pay in work for a better one. I don't want to beg; and if you will give me a chance, I think I can show you that I am willing to work for all I ask for."

The appeal was more than I could stand. I replied, "Why, yes, friend, I will give you something to do, to pay for an old coat," and I set him at work piling green basswood plank. Perhaps I need not tell you that this was a job that the average tramp would soon slip out of. But our friend didn't slip out of any thing. He took hold and worked so well that the men with whom he was working wished me to let him keep on a while. I asked his name, and told him that, if he worked as well as he had so far done, we could probably use him for a week or two, provided he could comply with the conditions of our establishment.

"Mr. Lewis, am I right in judging that you are or have been a drinking man?"

"Mr. Root, you have been very kind to me, and I will tell you the truth. I do get on a spree occasionally."

"Well, my friend, you probably use tobacco."

"Why, Mr. Root, I do when I can get it; but I have been so very low down lately, that I have not had any money to buy it."

"Well, now, perhaps you won't like to work for us when I tell you that we employ no man who uses whisky or tobacco in any form. If you think, however, it would be a good thing to break off all these things, and try to be a temperate and upright man before God and your fellow-men, we shall be glad to have you stay."

He promised to try it, and said he had worked at places before where they had the same rules. When I suggested that he lost his place by his habit getting the better of him, he acknowledged it. Sunday afternoon I called at the place where he lodged, and asked to go up into his room. I had before urged him to come to meeting. What do you think I found him doing? He was working slowly and painfully with needle and thread, trying to darn up his old coat so it would be fit to go to meeting after dark. He looked up at me with a frank, honest look, that I think was truly genuine, remarking, "Mr. Root, now may be I a'n't doing just the right thing, to mend my old clothes on Sunday; but I do it solely that I may be a little more presentable at meeting to-night. If you think I am wrong, I will stop it in a minute."

I replied at once, "No, no, my good friend, go on with your mending. It is all right, I am sure, in the sight of God; but while you work I want to talk with you a little."

I had won his confidence, and he told me of a wife and two children in England. They did not use him well, and he had come away off across the ocean. I suggested that it was on account of drink, and he finally admitted that perhaps it was. He had had good situations as stone-cutter, and had earned good wages; but he always lost one place after another, sooner or later; and when I found him he had spent one night in the infirmary, and then started out again in the cold wintry weather, to find some place where he might work until whisky should cast him out again. I held up before him the cross of Christ, and the Bible promises. When I asked him to kneel with me he replied, "Most certainly, Mr. Root," and quickly got down by my side while I prayed for him and others like him. The tears ran down his cheeks; and although he didn't promise much, he gave as sure evidences to me as I think I have ever seen, that he was truly penitent. He attended our Murphy temperance meetings, and went about, day and night, with a blue ribbon on his coat. I told the story to some friends, about his darning his old coat that Sunday afternoon, and we soon furnished him quite a respectable drab coat and vest, which were given him without any charge. He seemed very grateful, and was, to all appearance, as honest and faithful as a man could be.

Last Friday morning, March 5, one after another told me that Mr. Lewis had broken his pledge, and was too drunk to be talked to. In the afternoon and evening, four or five of our young Christians—yes, and some old ones too—hunted him up and tried to reason with him. Of course, our frank, honest, faithful friend was gone. Another light blazed from his eyes, and another spirit had possession of his faculties. He seemed possessed of a devil, as we read about in the Scriptures, in olden times. Saturday afternoon, after I came home from church, I was told he wanted to see me. I knew what the matter was, for I had told the time-clerk not to pay him wages while he was intoxicated. He demanded his pay. As I knew it would be used for buying more whisky, I objected. I finally told him in plain terms why I could not pay him his money. I asked him if he would tell me where he got the wherewith to get drink. At this remark it seemed as if Satan himself blazed forth from his eyes, as he refused to tell; and he added something like this: "Mr. Root, if you think you can keep back my pay, just try it on." And then he turned on another strain, and begged piteously for even two dollars, and prayed for Heaven's blessing to come down upon me if I would grant his request. I told him I would give him all his pay if he would promise me, even while he was intoxicated, not to drink any between then and Monday morning, and then come to me. He objected, and argued; and I believe now the man is truthful when in his right mind, and, that even while intoxicated, it was a hard matter for him to break his word. At length he gave me the promise and got all his money, except his board-bill, which the landlord where he boarded asked me to keep back. As I gave him the money, I asked one of the girls to bring me a good long piece of blue ribbon, and I tied it in the button-hole of the coat we had given him, hoping it might help him, and help the saloon-keepers to keep temptation out of his way. He went away pleasant and good natured, thanking us all. Had I done all that a Christian ought to do, according to Bible precepts, for the stranger that came to our gates? I had tried my weak hand in coping with Satan and the powers of darkness; and although it had amounted to but little or nothing, I felt that I had done the best I knew how, according to the best of my poor wisdom. For the sequel to this sad little story, see Our Homes, in this issue.

A SWARM BECOMES ENRAGED, AND MAKES A FURIOUS ATTACK.

DURING WHICH HALF THE BEES LOST THEIR STINGS AND THEN LIVED THREE WEEKS.

ON page 70, 1886, Ernest asks: "Does any juvenile, or anybody else, know of such a case, as that a bee lived two days or after?" Well, I once had a swarm of bees whose queen I bought of a man by the name of Good, somewhere in the State of New York, in the year 1868. I bought her for a pure-blood Italian queen; and though her bees were most beautifully marked, I have often thought they might be mixed with the Egyptian variety, on account of their inveterate hostility when they swarmed. They were not very ill to handle at other times; but when they swarmed they would hunt everybody and every thing—dogs, cats, horses, and chickens, and sting them with vengeance. On one occasion I was sitting in the door of my residence and saw them commence to swarm. I got up immediately and started to get a hive; but by the time I was half a dozen steps from the door they

ATTACKED ME IN GREAT NUMBERS.

I then returned to the house and procured a bee-hat, and gloves with long gauntlets; and having donned the aforesaid bee-apparel, I again sallied forth and was met by thousands of infuriated bees which stung me through my shirt, and stung my gloves and left their] stings so thick on my gloves and hat that you could not touch them with the end of your index finger without putting your finger on a sting. I did not count them, but I am satisfied that two thousand would not cover the number. An Irishman came to me at the time, and was stung in like manner. When he first made his presence known I said to him, "Tom, you had better go to the house; these bees will sting you to death."

"Oh, no; the leetle fellows would na hurt a body;" but about that time I heard him cry out, "Och! houly Moses!" I then looked around, and he was walking off slowly, scraping them off by the handful, first with one hand and then the other.

In one hour after they were snugly hived, they were as tame and submissive as before they swarmed. I observed them closely every day for two or three weeks. At first there appeared to be nearly or quite as many stingless bees at work as those unharmed by the loss of their stings. I am satisfied that some of those

STINGLESS BEES LIVED AT LEAST THREE WEEKS.

But what was most remarkable, I at that time kept a trough in a convenient place filled with urine, and in which about half a teacupful of salt was dissolved; and on the next day after the swarm came out I happened to pass this trough of stink-bait, and was surprised to see great numbers, perhaps a quart, of these stingless bees sucking at the stink-bait. I afterward went nearly every day to see and watch or observe how long they would go to it, and found them there in great numbers, gradually decreasing every day for some three weeks; so I am satisfied that a bee, if left at liberty, will live about or nearly as long after losing his sting as he would otherwise have lived.

Further, I was once put on a committee, with two or three other gentlemen, to investigate this matter. I took a small nucleus hive, only some 4×3×5 in. deep, filled with comb honey and some eggs and a young queen, and about 100 stingless bees, and moved them 1½ miles. They lived till some of the brood hatched to take their place, but I think salty stink-bait, or some other medicine, is actually necessary to their existence. JOHN L. GREGG.

Tempe, A. T., Feb. 2, 1886.

You have given us some very valuable facts indeed, friend G., that bees, after the loss of their stings, if allowed their liberty, have lived and gathered honey for some time afterward. Your experiments seem almost conclusive, that the loss of the sting does not materially shorten the lives of the bees, providing they are allowed their liberty. It seems to make considerable difference whether these stingless bees are confined, or given their freedom. I have found, however, by experiments recently, that single bees, without any bodily injury, will live four or five days, and even a week; but that a dozen or so together will survive sometimes three weeks. If the juveniles had caged their stingless victims with other bees, their reports would probably have not conflicted with yours; at any rate, their stingless bees would probably have lived longer. —You will notice that your conclusions in regard to salt and other like deposits are in line with the suggestions expressed by friend Greer, on p. 178 of last issue. As to whether the salt had any curative properties upon the bees above alluded to, might be a question. Has any one had an experience similar to the facts as given by friend G.? One or two more such would settle this problem of stingless bees. ERNEST.

JUVENILE·DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

"A chiel's amang ye takin' notes;
An' faith, he'll prent it."

HONEY AS A REMEDY FOR COLDS.

I HAVE a question that I wish to ask the mammas, and the little folks are to do the reporting in GLEANINGS. Much has been said in praise of honey as a remedy for coughs, croup, and sore throats. The question, then, or problem, if you choose, is this: Is honey a valuable and effective remedy for colds? or are its supposed curative properties a mere whim? During the month of March, when colds of all kinds are so frequent among our little folks, and older ones too, there will be a good opportunity to make a careful test. Perhaps many of our mammas are already satisfied in their own minds. From my own observation, California honey will seemingly check or stop a hard cough, when basswood honey has no effect. I want the juveniles to report, also, what kind of honey seems to be better than others for colds. Does California honey seem to have special virtue in its curative properties? Let us have no guesswork; but if honey is a valuable remedy for colds, as is the general impression, then we surely ought to know it. To illustrate the difficulty of deciding correctly in this matter, pardon me for telling you a little incident of my short married life. Now, I haven't any Huber of my own from whom to draw my illustration, but we have a little nephew, Arthur, staying with us. One night he had the croup, and neither myself nor my wife knew what to do; so we just stood and looked at him, while trying in vain to remember what our mas had done when we were little and had the croup. We had plenty of honey in the house, but we never thought of that. Finally, Mrs. R. said she had seen somewhere, that they gave ground cheese-rinds and hot water. This she quickly prepared and gave him. Under the seeming stimulus of this dose he got better. If we had given him honey, and the results had been the same, we might have thought there was great virtue in honey. At another time when he had the croup, we gave him nothing, and by morning he was better. In the first place, supposing we had given him no dose, what would have been the result? Our mammas will see the difficulty of deciding whether a certain remedy does or does not prove effective. Repeated trials, however, as doubtless mothers have had, will very likely decide pretty closely. How many reports shall we have next month, for or against the curative properties of honey? This is a matter upon which, with the help of your mammas, many of you can report.

ERNEST.

"HONEY-DEW A GREAT HELP."

We children watch the bees gather honey from the clover-blossoms. Pa says honey-dew is a great help to them. I was in the yard last summer, and a bee stung me on my foot.

Smithville, Mo. HARDY and NELLIE JENKINS.

BEES IN OREGON.

My father and the boys have 73 stands of bees and I have two. Last winter it was snowing the day after Christmas, and this year it was sunshiny. The bees were flying on the 26th of December. I like bees, but I do not like honey.

Harmony, Oregon. HESTER RUSK, age 10,

DO THE LARVÆ ABSORB OR EAT THEIR FOOD?

My pa has 50 swarms of bees, and has them in winter quarters. I have a little brother four years old. I am interested in bees, and I want to ask a question. Do young bees eat in the cell, or do they absorb the food? Why do they turn their head from the food. NICHOLAS JONES, age 13.

Delaware, Ohio.

I consider your question in the department of Our Own Apiary, which see.

ERNEST.

WHITE HONEY IN A BEE-TREE.

My uncle, F. H. Gorton, is a bee-hunter, and he found a tree on our place with nearly 50 lbs. of nice-flavored honey, and all white comb, arranged up and down in the tree as nicely as he ever saw in a hive. He says he never saw any like it before, and he has dealt in bees always.

MAUDIE H. MORENUS.

Sherburne, Chenango Co., N. Y.

HOW PHEBE GOT HER THUMB STUNG.

I tried to make my bee sting a piece of cloth, but it stung my thumb, at 12 minutes after 11 o'clock in the morning. Mother put it in a cage, and I gave it some honey. It died some time in the night. The next day I tried another bee. It lived 7 hours. It looked like an old bee when we got it. I can not write much, because I could not go to school last summer, so mother is writing for me. I can do a good many things to help her, through.

Whitby, Ont., Dec. 28, 1885. PHEBE ORVIS.

A BEE LIVES 58 HOURS CAGED ALONE.

We got our bees on Christmas morning. Mine stung me on my wrist at five minutes past ten. It lived 58 hours. We had two bees left when we got through, and we put them in a cage together. They went to fighting at once, and lived one hour and ten minutes. I saw through the microscope a drop of poison on the end of a sting. We had about 3000 lbs. of honey last season. We have two colts. One of them will follow me around when it wants any thing. SPENCER ORVIS, age 10.

Whitby, Ont.

We now have record of a bee living 58 hours or nearly two days and a half. Next time you try, cage with other bees.

ERNEST.

WATCHING THE TOES OF THE LITTLE BEES.

I wanted a bee too, so Spencer helped me, and made one sting a piece of cloth at 22 minutes past 11 o'clock, and it lived till 9 o'clock the next morning. I saw it put its toes around the wire of its cage to hold on when it walked. I have a slate and book, but I can not write, so mother has written this for me. BERTHA ORVIS, age 5.

Whitby, Ont.

It is real funny to see the bees' little feet trip over the wire in the cage, is it not?

ERNEST.

IS PACKING IN WINTER NECESSARY?

One year ago last fall my pa had 9 swarms of bees, and my sister had 2 that my pa's cousin gave her. Pa packed them all but two—one of my sister's, and one of his own. His cousin said that they would do better without packing, but pa thought not; but seeing that he gave my sister the bees, pa left one of them out, and one of his. Both of them died, and two more besides. The bees died all around us last winter very badly. We have now increased them to 19, and have them all packed. We use the Simplicity hive. LOUISA E. GREEN, age 11.

Lyons, Ohio, Feb. 3, 1886.

Thank you, friend Louisa, for the facts you give. Then you think it does not pay to leave bees on their summer stands during winter without being packed, do you?

ERNEST.

SOMETHING ON BEE-STINGS, FROM AN OLD BOY.

I see by the last issue of GLEANINGS that the bee-sting business is not yet settled. Well, little boys and girls, I will tell you what I know about it, and what I don't know. Several years ago, while working in the woodshed, I saw a bee hovering about an old piece of comb that had carelessly been left there, and I noticed at once that she had lost her sting; but, for fear that I might be mistaken, I caught her and made a careful examination, and am entirely satisfied that she had no sting, although she appeared to be in splendid health, and as lively as a *whole* bee. I do not know what she was looking for, but suppose it was for honey. But now the question arises, How long was she stingless? That's what I *don't know*; but from all appearances, she had been so for several days.

I want to say to Emma Jansen, that I also have at least one carp that does not bury itself in the mud in winter. I can see it almost every day, as I have it in a small pond by itself. I am a small boy of 26 years, and weigh 155 pounds—small compared with some others. HENRY.

Your observation is in line with friend Gregg's article in another column, and I think it is quite likely the bee you mention had been without its sting for some days. On the other hand it seems to be pretty well established that, the stingless bees will not live long when confined. ERNEST.

THE HONEY-PLANTS OF GEORGIA, AND HOW SOON THE BEES BEGIN TO WORK THERE.

There are lots of honey-bearing trees and plants here. Among them are the honey-locust, persimmon, black gum, sourwood, and others. The cotton plant produces some honey.

Bees begin to bring in pollen from the 10th to the 15th of February. Our bees are in good condition, with plenty of honey. We had lots of cold weather last fall. The thermometer has been down to 16 above zero, and as many as three mornings together, below 20. **FLORENCE E. KELLEY**, age 12.

Harmony Grove, Ga.

SHALL WE SELL HONEY TO SALOON-KEEPERS ?

Raising bees has been very profitable to my father. Unfortunately, he has to sell most of his honey to bar-rooms. Well, I suppose they might just as well use honey as sugar. There is no law to prevent the use of liquor. My father has 64 hives. No one in the neighborhood has as many.

LOU FRIEND, age 13.

Chester, Va., Feb. 8, 1886.

Friend Lou, there is a moral point involved in your letter. Of course, I would not dictate for your father, but I think I would sell the saloonists none of my honey, providing they intended it for use in their traffic. If they intend it for an honest purpose, I do not know that I should hesitate to sell them all the honey they wanted. **ERNEST.**

HOW THE CHROMOS AS PRIZES ARE APPRECIATED.

I received a lovely panel chromo from you; many thanks for it. Brother Fred has his bees packed. He has the hives set in big boxes, and chaff around the hives. He has a house-apiary. I like to work with bees, but do not like honey. The first swarm Fred ever had, he had in a box hive, and soon he sent and got one of the Simplicity hives, and transferred them into it. He likes the Simplicity better than any other style of hive.

Woodstock, Ohio. **NETTIE H. CRANSTON**, age 11.

CATCHING SWARMS IN HIVES TIED TO A TREE.

My papa has 10 stands of bees, and loves to work with them. I will tell you how he caught three good swarms. He took the stands that other bees had died in, and which had old comb in, and tied them up in trees, and the bees went into them. Papa lost one good stand of bees which had 17 lbs. of honey. He thinks they froze to death. New Orleans sugar is very good to feed them in winter.

Smithville, Mo. **ESTELLA JENKINS.**

Thank you, little friend, for the item that you give. If you could get the bees to go into the hives thus prepared, and the hives could be raised or lowered easily, it would be a capital plan for catching swarms; but I should be afraid that the bees would not always go where we wanted them. **ERNEST.**

A JOB AT FEEDING SECTIONS; HOW TO PACK HIVES FOR WINTER.

Pa has a lot of bees which were flying about two weeks ago, all living and doing well. Pa has about completed a new building, and machinery for making hives and one-piece sections. When school is out, my pa offered me a job to feed the section-sander with buckeye sections. I like to see them come through on the other side. They look beautiful and white. Pa has promised to let me pull the rope for the first time on the big engine-whistle that is now in the new building. In the fall, coming on winter, we took fence boards and stakes. We drove the stakes along in a row close to the hives, and set the hives close together. Then we took clover straw and put it in between the hives behind, and boarded the whole around the outside.

Ada, O., Feb. 22, 1886. **RAY MURRAY.**

BEE-KEEPING IN FAR-AWAY IRELAND, AS REPORTED BY A JUVENILE.

Father has given me leave to write you about his bees. He was in America for some time, and came home twelve months ago, and commenced bee-keeping about April, by buying eleven straw hives of bees, and he drove them out and put them and combs into wooden hives, what he calls eight-frame Langstroth hives. He has twenty of them now. There is nothing but straw hives about here, and all black bees. Father has had several Italians from America, but the most of them were dead. He has six living; they were about 14 days coming. He got three on November 30, but two of them were dead.

There was a great buzzing in swarming time. Father clips the queen's wings, and when a swarm goes off he catches the queen and puts her into a cage and moves the old hive away and puts the new one in its place, into which the swarm goes when they miss the queen. He then lets the queen in with them, and puts the hive in its place, and the old one back. It is very nice to see them rushing into the hive.

Last season was good for honey, but father did not get much. He says he was too late in starting.

We have hardly any winter here at any time. Primroses, wall-flowers, etc., are out in bloom now, and every thing is looking very green; but we have a great deal of rain at all seasons, which father thinks will be a great drawback to successful bee-keeping in this country; but he is going to keep nothing but Italians, as he thinks they are the best. They are a very pretty bee, and I like them, for they seem quiet, and do not sting so much as the black ones. Father gave me a swarm which he took out of a chimney where it had been for some time. My sister has a hive too. The swarm came from somewhere, and settled on a bush close to the other bees, and father put it into a hive and gave it to her and we are very much pleased with them.

CHARLOTTE R. TURNER, age 10.

Revlin House, Donegal, Ireland, Jan. 6, 1886.

FROM 25 TO 51, AND 2900 LBS. OF HONEY; REPORTED BY A JUVENILE.

My father wintered 25 colonies during the winter of 1885, and they increased to 51. He took off 2900 lbs. of comb honey, and last fall he doubled them back to 45. He has seven of them out of doors, and the rest in the cellar. Father makes his own hives and sections. He uses the Langstroth Simplicity hive. He is going to make about 5000 sections this winter. He is going to give me ten cents a hundred for all I nail together. Father takes GLEANINGS, and thinks it is a good paper. I claim the Juvenile Department, and I like to read the letters. I have one colony of bees. They made me 100 boxes of honey. I like to help father among the bees, but I don't like to have the bees sting me. I got stung six times at one time last summer. Father went up to Skowhegan this year to the bee-convention, and he saw Mr. J. B. Mason and sons of Mechanic Falls, Me. I can't think of any more this time.

George F. Greely, age 13.

Clinton, Maine, Jan. 31, 1886.

Thank you, friend George, for your very full report. I judge that you take considerable interest in your father's work. When fathers can get good substantial help from their boys, they can expect to attain some degree of success, as did your father. You say you "can't think of any more." It is not long letters so much we want, but it is a good deal in a little space, and I think you have succeeded pretty well. We should like to have you report in regard to your father's bees next season. Ernest.

STRONG SWARMS READY FOR THE FIRST FLOW OF HONEY.

Mrs. L. Harrison sent me a colony of pure Italians. They were weak when they came, and we built them up with other brood; when they got strong we made an artificial swarm, and then they built up very strong with plenty of stores, but no surplus. Those that had strong swarms early for the first flow of white clover were all that got any surplus in this section of country. Auntie L. sent me an A B C book, about the same time she sent the bees. Willie Simonton.

Memphis, Mo.

CARP, SWEET-POTATO VINES BLOOMING, ETC.

Pa has between 65 and 70 carp minnows, and they eat a piece of bread as large as my hand, every night. They eat more at night than in the daytime.

Grandma's sweet potatoes bloomed last summer. The reason I speak of them, is because I have seen inquiries in the papers as to whether the sweet potato vine blooms. Ma says that there would be as many as twelve blooms on a vine not more than two feet long. She says that she has heard of but one other instance where they bloomed so profusely, and that was at a neighbor's a few years ago.

I received Ten Nights in a Bar-Room, and read it with great interest, as did all the family, and I loaned it to a neighbor, and she loaned it to another neighbor; and as most of the neighborhood favor dram-drinking, I hope it may do some good while away from home.

What would it cost to send a few beechnuts in the burr, for seeds? I have never seen any, as they do not grow here; but I have heard pa and ma speak of them, and I should like to see some.

Amy I. Holleman, age 11.

Wager, Benton Co., Ark., Feb. 14, 1886.

We did not succeed in getting any carp minnows last year from our carp-pond. As about a dozen large mud-turtles had succeeded in getting into the pond, we rather thought they had eaten all the spawn, or fish-eggs. We had been in the habit of feeding the carp crackers toward evening, and by and by the mud-turtles learned the trick of grabbing the crackers too. A casual observer would hardly notice this sly movement of the turtles, but a little close watching shows how nicely they can gobble up the fragments that are thrown out. I determined that I would shoot every one of them if possible, and accordingly on the 4th of July last, with rifle in hand, as soon as one stuck his nose out of the muddy water, I let fly a bullet, knocking said nose, head, and neck, into—well, you know what, boys. In this way I disposed of over a dozen, and, so far as I know, we have not been troubled since. If any one is annoyed by these in his pond, I know of no better way to get rid of them.

In regard to the beechnuts, Amy, you can get some relative, where they grow, to send you some. The postage will be one cent an ounce, and for 10 cents postage you can probably get all you need. Ernest.

GOING OUT OF THE BUSINESS—HONEY TOO CHEAP.

Noticing that you wanted the juveniles to send in reports about how long a bee would live without a sting, I thought I would send mine. A few days ago when the bees were having a fly, ma was in the bee-yard about ten minutes. When she came in there was a bee on her back that had just lost his sting. I took care of him, and, counting the ten minutes ma was in the bee-yard, he lived just three hours. Pa has 32 swarms of bees. He has lost one nucleus this winter. The rest are doing well. Last spring ma was in Blasted Hopes, but pa said we would try again. Last summer the bees did very well. Pa says he is going out of the business, because honey is too cheap to eat. Cora Snyder.

Corey, Mich.

Friend Cora, we are sorry to hear that your papa is going out of the business because "honey is too cheap." Ought we not to rejoice that there are hundreds who can now enjoy one of God's choicest sweets, where they could not before when honey was 25 and 30 cts. a pound? Perhaps the false statements that you have been reading about may have had something to do with making "honey cheap;" but we have good reason to think that people will soon learn the true source of honey. Again, there are thousands of people who hardly know what honey is. Let us stir ourselves, and help papa to sell the honey around home instead of sending the whole lot to the city, where honey is hardly wanted at any price. Don't you see that the more honey we send into the city, where the sale is slow, the lower the price will be there? Let us see how many uses we can make of honey; and when the city folks are willing to pay a fair price, we will send it to them. At the head of this department you will see what I say about honey as a medicine for coughs and croup. Now, perhaps the very cheapness of honey will so introduce it to the people that they will conclude they must have it, and the price will then rise accordingly. No, friend Cora, don't let your father give up the business yet. Ernest.

HOW MANY BUMBLE-BEES ARE THERE IN THE AVERAGE SWARM?

My pa bought some bees in a soap-box, and Gleanings told him how to transfer them; but he forgot that he was ticklish about the knees. The bees found that out, and, well, pa will now wear garters outside his pants near his shoes. I like to frolic with the bumble-bees. I read the piece about jugging the rogues. I used to pour hot water in their ground-nests. Last summer I found a nest in the front yard, and, in the cause of science, to find out the number of bees in a nest I borrowed ma's round wire fly-trap with a tin top. I made the hole in the cone a little larger, and set it over the hole in the ground just at dark. Next day I caught 160 bumble-bees. The next nest I caught 171. The next nest I caught 47, but they were whoppers, with yellow mufflers on.

We have a judge in our town whom we call the bumble-bee judge, because he for a little money tried to defend a black man found killing turtle-doves, and the judge wanted the witness to say that the man was just chasing bumble-bees. The black man is now in State prison for another crime, and the judge goes to Utah, Warren Co., Ill., sometimes, to draw a big salary. **Hadley Renshaw**, age 12.

Terre Haute, Ind.

Thank you, friend Hadley, for the facts you bring out in regard to the bumble-bees. I used to rob their nests sometimes, but I had no idea there were so many. Did you find very much honey in the largest nest? Aside from the fun, I never thought the amount of honey paid me for the trouble. Altogether, I do not know but that it is rather cruel to rob their nests, if fun is the only object; of course, they may build their nests where it is desirable to get them out. —Your fly-trap is similar in principle, if I mistake not, to the Alley drone-trap; and it is possible that our friend may have got his idea of the wire cone from this fly-trap. **Ernest.**

FIVE CENTS FOR REPORTING EVERY SWARM THAT COMES OUT.

A year ago this winter papa lost almost all of his bees. When spring came he had but 37 colonies left out of 79. From these we got only 1300 lbs. of honey —600 lbs. comb honey, 700 lbs. of extracted honey. He has kept some bees down cellar this winter, and some days it was so cold he had to have a fire down there. When papa had to work in the field he told me if I would watch the bees he would give me five cents for every swarm I saw coming out; so when I saw them coming I would run and call him, and he would come and hive them. I go to school every day. I have language lessons, and in that way I have learned to write letters. Last month my average on examination was 94¼, the highest of any in school. **Mabel Emmons**, age 8.

Tampico, Ill.

I heartily indorse your father's plan of giving you five cents for every swarm you saw coming out. Even when I was quite small, "my pa" generally rewarded me in some such way for little services that I was able to render. As mice sometimes made destructive work with combs stored away for the winter, I was allowed five cents for every mouse I caught. Each additional five cents gave me a new impetus for ridding the barn of the "pesky varmints." As we lived in town, it was my allotted task to pile wood and hoe the garden—two things that I detested above every thing else. One day father said to me, "If you will hoe that garden so that I can not find a teacupful of weeds, I will give you a croquet set." All at once I took keen pleasure in "seeing things grow." I was up in the morning, and at work again at it after school; and when by the sweat of my brow I had a clean and handsome garden, with what pleasure I showed father and mother what I had done. The result was that we had an abundance of vegetables of all kinds. Why, I believe I enjoyed that garden more than the croquet set which I obtained afterward. It pays every time to reward children with some small gift; and it need not necessarily be a croquet set either. Piling wood, hoeing in the garden, helping papa to extract, will thus become keen enjoyment; where before it was any thing but pleasure. **Ernest.**

"HUBER AND HIS PA" AS THEY APPEAR EVERY DAY AT HOME AND IN THE FACTORY.

Yesterday, in Gleanings, I saw in the picture of your greenhouse, a man and a boy. Are they Huber and his pa? I should like to know. Pa takes Gleanings, and we like it very much. Ma thinks it is interesting to read in Our Homes.

Sylvester Z. Paulus.

Stone Creek, Tus. Co., O., Feb. 23, 1886.

Yes, friend Sylvester, "Huber and his pa" stand near the greenhouse in the picture. If you turn to the editorial column of the same issue you will see that the picture is there explained. Of father, if the engraving is held at arm's length, it is a very correct likeness as he appears every day in the factory and on the grounds. He is somewhat bald-headed, you know, so he has to wear a heavy fur cap in winter, such as you see on his head. Occasionally something comes up that "needs to be seen to right away." Often it takes me a good while to find him, and sometimes after a search in vain through the various departments of our factory, as a last resort, I take a look from one of the upstair windows, and away to the other end of the honey-farm, very likely, I catch a glimpse of that identical hat and its possessor, possibly emerging from a piece of sweet corn, or from a ditch where an underdrain is being put through. After he has been reading letters he gets tired (for he has not the endurance that he once had), and for recreation he busies himself in the garden where, perhaps you are aware, he finds keen enjoyment. Well, during week days he doesn't change his general appearance as seen in the picture very much, except once in a good while he gets "awful" muddy; and as he resumes his letters, you would hardly take him to be the boss of over one hundred hands. Huber's mamma sometimes has to give him a good talking-to for being so careless; but when he has been digging in a muddy ditch, and thereafter returns to the letters, it is not easy to maintain the same appearance always. You know how it goes, boys, from the playground to the schoolroom.

As to Huber, I do not think the picture represents him very well. It is a difficult matter for the engraver to correctly represent a child's features. Huber is quite fond of following his pa out on these excursions on the farm. Lately he has taken a great liking to watch the men work at their various machines—at one time in the wood-working department, at another in the machine room. Once we caught him walking under the belt of the great fly-wheel of the engine. We have told him he musn't go there any more, for it would "make the b'ood come" if he did. This is the only way we can explain the terrible consequences. He has been very careful lately. **Ernest.**

TOBACCO COLUMN.

I UNDERSTAND you offer any man who will stop using tobacco, a smoker. Well, I will comply with those terms. I make you the regular promise, if I ever commence smoking tobacco again, I will pay for the smoker.

Glenwood, Pa., Oct. 17, 1885. C. D. BENNETT.

You said you would send any one a smoker who would stop using tobacco. I stopped chewing one year ago, and went to smoking. Since last May I have not used it in any shape. If you see fit you can send me a smoker. If I commence using the weed again I will pay you all you ask for your smoker. L. F. COUSINS.

Utica, Pa., Dec. 28, 1885.

I received my watch a few days ago in good order; but last night I hung it up and when I got up this morning I found the crystal broken, from some unknown cause. I suppose the glue must have frozen and caused it to break. If you will send me a new crystal, I will promise to quit using tobacco. CHARLIE HARRISON.

Collinsburg, Bossier Parish, La., Feb. 1, 1886.

I notice that you will give a smoker to all who stop using tobacco; and as I have been using it, I think I can stop for a smoker. I have two colonies of blacks, which I expect to Italianize in the spring. It is agreed, that I pay you for the smoker and the postage, if I ever use a crumb of tobacco again.

Rockingham, Va. W. O. ROUDABUSH.

A NEIGHBOR HAS QUIT.

I have 24 stands of bees, but I think they are poor pay in this county. I never use tobacco. My neighbor, however, has a few bees, and has lately quit the use of tobacco. He asked me to write to you to send him a smoker. His name is H. L. Revely. Since he quit the use of tobacco I think he is a nice man. If he is ever guilty of using it again I will see that you get your pay for the smoker.

Austin, Lonoke Co., Ark. E. M. BARGER.

ONE WHO HAS USED THE WEED 15 YEARS.

I notice from GLEANINGS, a copy of which was loaned me by a friend, that you offer free to any one who will give up the use of tobacco, one of your smokers. I have used tobacco for fifteen years, and at one time was an inveterate smoker; but I have given it up; and if you feel inclined to send me a smoker I shall feel grateful; and should I again take up the use of tobacco I agree to remit you the usual price of a smoker.

Boyce, La., Nov. 22, 1885. W. P. BRADFORD.

MIXING BUSINESS AND RELIGION.

I am very much pleased with the Christian tone of your magazine; and as to mixing religion with business, I say the more the better; and there must be something wrong with the business that is ashamed or afraid of religion.

I might say something in regard to using and selling tobacco—the Lord saved me from using it several years ago, and the clear light revealed that it was as great an evil to sell as to use it. I find it is just as easy to do a *clean* business, as any other, and much more in accord with a clear conscience and Bible truth. There is victory for every slave to the habit, in Jesus' name. J. E. BRISTOL.

Harpersville, N. Y., Jan. 21, 1886.

KIND WORDS FOR GLEANINGS.

I like GLEANINGS better every time I get it. I let my neighbor read it, especially the 15th, or middle numbers, and he, too, thinks it splendid. Well, my neighbor who got a smoker when I did, for quitting the use of tobacco, I am sorry to tell you, has gone to using the weed again; and as soon as I can get up a club of a few names for GLEANINGS I will send the money for the smoker. I still "hold the fort" in regard to tobacco, and hope I always may.

Henton, Ill. F. P. HISH.

I have taken GLEANINGS for the past six months, and I think it is a very valuable journal, especially Our Homes and also the Tobacco Column; in fact, it is a fine work all through, and is doing much good. May you live long to continue it. I have commenced keeping bees, and I enjoy it very much. I commenced last spring with two stands, and have gone into winter quarters with 11. I am making chaff hives for next season. May I ask what is the best permanent packing—chaff or sawdust? I have quit the use of tobacco, after using it for ten years, for good. If you think me worthy of one of your smokers you may send me one. If I ever use tobacco again I will send you $5.00 for it. WM. D. SOPER.

Jackson, Mich., Dec. 1, 1885.

We prefer chaff to sawdust for packing.

KIND WORDS FROM OUR CUSTOMERS.

I have received the A B C of Bee Culture, and it is the best bee-book that I have seen.

Douglas, Putnam Co., O. H. D. FRIEND.

THAT CALIFORNIA HONEY, FINE.

That California honey is fine. That is the first extracted honey that people ever saw in our town, as I have not used an extractor yet myself. Parties who have bought of that honey praise it wonderfully. E. SALISBURY.

Ossian, Ind.

WELL PLEASED WITH THE GOODS.

I received the goods yesterday. They came through in good condition. I am well pleased with them. I think the smokers can not be excelled. Please accept many thanks for sending the order so promptly. I have found that, in sending for small orders, there is very little difference in either express or freight to this place, except in time.

St. Joseph, Mo., Feb. 27, 1885. JOSEPH F. AERY.

OUR JOB WORK GIVES GOOD SATISFACTION.

The package of circulars and envelopes came to hand yesterday, and they are a very fine job. We are highly pleased, both with the work and the very reasonable price charged, and we feel sure they will greatly help our trade. The cut which you had made for us is a beauty, and shows the working of the machine to perfection. G. W. STANLEY.

Wyoming, N. Y., Jan. 8, 1886.

A PREMIUM FOR THE SECOND LARGEST CLUB FOR GLEANINGS FOR 1886.

Friend Root:—I will second Mr. P. L. Viallon's offer as per last issue of GLEANINGS, by offering to the bee-keeper who gets the second largest number of subscribers for your journal, between now and the 15th of June, one of my two-frame white-banded albino nuclei, with untested queen, to be delivered June 15, 1886. I will also *give* one of these nuclei and queens to the bee-keeper who sends me the *first* order for a nucleus after this date, and accompanied with cash ($3.00), both to be delivered June 15, 1886. CHAS. H. SMITH.

Pittsfield, Berkshire Co., Mass., March 4, 1886.

[Many thanks, friend S.; but your last offer, it seems to me, might not fall to the one who made the first order, but the one who lived nearest to you; for parties a good way off might not have a chance to have their orders reach you as soon as those near by.]

OUR HOMES.

So is he that layeth up treasure for himself, and is not rich toward God.—LUKE 12:21.

IT was Sunday evening, March 7, as I sat down to my secretary, where I read my agricultural papers during week days; but I didn't look at the agricultural papers at all, even though a great heap lay there awaiting my review; for I have always noticed that I don't feel as light-hearted, and free from any twinges of conscience, when I read such things on the Sabbath-day as I do when I read the *Sunday-School Times* or the Bible. I noticed that the lesson for the following week was from the book of Esther, and so I took my wife's little Bible and read the book of Esther clear through. By that time I remarked to her that I believed I would go to bed, as I was getting so sleepy. The print of her Bible is rather fine; but for all that, I have never used spectacles, even though I am 46 years old. May be the fine print made me drowsy before my usual bedtime. Perhaps it was in a sort of drowsy way that I asked God's blessing as we knelt together. I did the best I could, any way, under the circumstances, and I think that God knows that I am ready to work for him with my whole heart, whenever he calls. I do not remember any thing more until my wife startled me from a sound sleep by asking what that light was out of the window.

"Why Amos, there is a great fire! and as true as you live, it is our warehouse!"

I remember she said something about the poor horses and our Jersey cow; and as I sprang from the bed, wide awake in an instant, I meditated running to the scene of the disaster without dressing at all; but in a small part of a second I decided it would be better to clothe myself so I could stand the weather, even if some time were lost. I had many times planned what I should do if the factory should be discovered to be on fire; but I had never thought of a fire starting in the warehouse, for no fire is ever kept there, and no lantern, even, had been there for weeks. It is out in the lot, as it were, alone, except for piles of dry pine and basswood between it and the factory. As I emerged from the house, a horse turned and faced me and snorted. It was "Meg." "Thank God," I thought, "Meg has escaped, any way."

About this time I began to hear the hoarse call of "Fire!" from neighbor to neighbor, and the first thing to be done was to give notice to the fire company. I mentally decided that this was of more importance than going near the burning building, to try to save any property. Too much depended on every moment of time to trust to anybody, and I started on the run for the engine-house; but just as I had passed the factory, Neighbor H. shot past me on one of his horses, yelling worse than a Comanche Indian. I didn't know before that any horse could go so fast, nor that any human lungs could utter such unearthly shrieks; but I mentally thanked God for the horse, for Neighbor H., and for his powerful lungs as well.

Now I want to stop a moment to tell you that Neighbor H. had a brand-new self-binder stored in a shed adjoining the warehouse, and this binder was not insured. Had he shot right down to the warehouse, with the assistance of neighbors there he could, very likely, have pulled his machine out. He thought of it on his way to the engine-house, but decided that the reaper would have to slide for the sake of saving the few minutes' time in getting the engine down to save my property. By the way, boys, doesn't that come pretty near loving your neighbor as yourself?

The boys who sleep in the factory were now awake, and yelling, after the example set them by "Uncle Hen," as Huber and the rest of the children call Neighbor H. I told one of them to stay about the factory, and then we went to see what could be done with the warehouse. You will hardly believe it, but by the time I got down there, it was pretty nearly a burnt building. Not only the million sections that we had been making ahead to fill your orders were helping to make the great conflagration, but there were all my tools and agricultural implements, and ever so many other things that represented the hard work of years past. Worse than all, a south wind drove the fire fiercely into the lumber piles, and it seemed for a time as if nothing could prevent it from sweeping clear to the factory, and licking that up too. How I ached and prayed to hear the roar of the fire-engine, indicating that a stream of water had started to the rescue! Finally it commenced coming, and hundreds of willing hands lifted the great hose toward the lumber piles. All at once the water stopped. In their zeal they had pulled the hose in two before it was fairly coupled together. A messenger must be sent back to the engine to stop the flow of water, while the hose was mended. Finally it began pouring a great muddy stream on the burning piles; but, to my great dismay, the fire seemed to burn just about as well with water on as it did without. The water was forced through the openings between the boards; but as soon as it stopped, even for an instant, out poured the flames again. The flames were within a few feet of our second warehouse containing our seasoned lumber and Simplicity hives; but it seemed as though even the fire-engine was powerless to stay it. But by this time men and women had formed lines, standing in the mud meanwhile, and pails were passed from one to the other, while this second warehouse was kept drenched on the roof, and along the sides and ends, by means of little fountain pumps. For hours they fought, making apparently but little headway; but the wind finally veered around a little, and a snowstorm set in, and—we, by God's providence, conquered.

Of late, my health has threatened many times to break down, and I began feeling that, if I would be of any use on the morrow, I must get some sleep. Many friends told me that this was the wise thing to do, after I was sure the fire was within bounds. I obeyed, and laid my head on the pillow. Now, it has always been said of me that one reason why I could stand so much mental strain was that I could go to sleep at any time, day or night. Was I equal to the task now? I began to feel that I was not, until I questioned myself in regard to God's promises. Whose property was it that was burning up? I held the title to it, and it was all paid for. Was it mine, or the Master's? I had often told him, on bended knee, to take me, and all that I am and all that I have, into his care and keeping. Here was a chance to practice what I had preached. "Seek ye first the kingdom of God, and his righteousness, and all these things shall be added unto you," came into my mind; and again, "The Lord gave and the Lord hath taken away; blessed be the name of the Lord." If it was through any fault of mine that the building was burning, I might lie awake and worry, or get up and right the fault. If, however, it was something I had nothing to do with, why should I be troubled? If the property was all in God's hands, and he had seen fit to permit it to be taken away in this manner, why should I worry or lie awake when rest was so much needed? "Behold the lilies of the field; they toil not, neither do they spin, yet your heavenly Father feedeth them." And, again; in our opening text the man whom Jesus told about had great property, and was obliged to build even greater barns; but he expected to get all his happiness and contentment and peace from the contents of those barns. If my hopes were planted on the contents of the warehouse, and sections by the million, then might I lie awake; but if they were rooted and grounded on the rock Christ Jesus, why should I not sleep as well as in any other time, when duty and friends seemed to point out that I should husband my powers to help others, by taking rest? The above reasoning took me, perhaps, five minutes, and I went to sleep as if nothing had happened. When the fire-engine stopped for a few minutes, however, I sprung up instantly. My wife asked what the matter was. I told her they had stopped throwing water. Can you imagine how sweet the sound came as the booming commenced once more? I afterward learned they stopped long enough to disconnect the hose and put it *under* the railroad track instead of *over*, so it should not be cut by an approaching train. One other stoppage happened, but I awoke as promptly, and commenced dressing until they got started again. Even while sleeping soundly I kept in mind that, if our city water-works should give out, the fire would be again upon us.

When daylight came, the flames still burned high, but they were held captive. Sure enough, the firemen had exhausted the water from the reservoirs, and they were obliged to wait until afternoon so that more could be pumped, and then, and not until then, was the fire put clear out.

Perhaps I might say, briefly, that our loss amounts to some ten or twelve thousand dollars. Insurance covers of the above a little less than five thousand dollars. As we have a great abundance of seasoned basswood and pine that the fire did not touch; better machinery than we ever had before, and I trust, too, a better-disciplined force of willing hands, we shall not be much if any behind on orders. The day after the fire, I gave the hands a talk at the noon service, reading from the book of Nehemiah about how they built up the walls when the gates were burned down by the enemy; and it seemed to take a happy hold of our little band of workers, so that we to-day, March 16, have quite a little pile of sections ahead, awaiting orders; and by working from daylight till dark, we think we can supply the wants of our customers, as if nothing of the kind had occurred.

Now, then, how did the building get on fire? Nobody knows. But in telling what we *do* know, it brings to me sadder thoughts, —a hundred times sadder, than does the thought of the loss of property or the loss of the lives of our domestic animals. When my wife inquired about our old trusty family horse, who has, for toward twenty years, been the faithful servant of the family, from the time when he used to bring my wife to church, from her home down by the river, until he took each new baby out for its first ride, allowing it to hold the lines, and drive, or to pick grass for him when he was older, sit astride his back, until he was, as it were, one of the family—when she inquired after the welfare of this faithful old friend, Uncle Hen showed her a blackened horseshoe. It was all he could bring her as a remembrance of the horse that had been her special property for so many years. The first neighbor who came on the ground when the building was burning, saw the doors of the warehouse open, and the two horses loose in the field. Poor old Jack! in his fright he ran back into the fire, and turned up to his old accustomed stall. Finding it full of smoke, with a snort he started for the other end of the warehouse. Being unable to get out there, he wheeled back and fell down inside, just before the door where he went in. Both horses had very strong leather halters on their heads, and the rings to the halters were found in the ashes by the manger, indicating, without question, as it seems to me, that somebody unbuckled the halters and slipped them off, turning the horses loose after they had removed the bar and opened the doors. It also seems as if the warehouse had been fired in different places. "An enemy hath done this," is the language of every one; but what *enemy* have I who should thus desire to destroy my property? taking the lives of the domestic animals, and endangering the whole of this part of the town? Whoever planned the scheme must have remembered that it was an exceedingly dry time, and that the wind was blowing pretty strongly right in the direction of those dry lumber piles.

Am I to blame for having such enemies? I may be, but it is not certain. It is a sad fact, that throughout our land there is a bitter feeling among some of the laboring classes against those who manage capital. Intemperance is a large factor in this trouble; and even now, while I write, the papers are full of accounts of strikes and trades-unions. How great, how *very* great, is the need of God's love in the hearts of both capitalist and laborer! Sometimes men who have been discharged for unfaithfulness, or for dishonesty, threaten to, and even do, set fire to buildings. Shall one who employs many hands, therefore hesitate about reproving dishonest or unprofitable hands? or, when he discovers that the example of *one*, is corrupting to a large number, shall he keep him, for fear of what he may do? God forbid! Where should we be—what would become of the laws of our land—what would become of our nation, in fact, should we cowardly back down and let evil rule? Shall we lie awake nights, and worry, because of this kind of wickedness? By no means. What did the Master say in regard to this matter?

> Blessed are ye, when men shall hate you, and when they shall separate you from their company, and shall reproach you, and cast out your name as evil, for the Son of man's sake.—LUKE 6:22.

He said, "Blessed are ye;" that is, when the persecution comes for *righteousness'* sake. The Savior lost his life because he reproved wicked men. John the Baptist was beheaded because he told a wicked king and the woman he lived with that it was a sin and a crime to do as they were doing. Two of our presidents have lost their lives because they held fast to that which was right. If this property has been burned because I have been vehement in regard to temperance—because I have been determined that no man or woman whose example is bad should persist in trying to lead these souls away *from* Christ, these whom I have been faithfully trying to lead *to* him, then should I rejoice, rather than to be cast down and sad. There is a strange verse in the sixth chapter of Luke, just after the one I have quoted. It reads this way:

> Rejoice ye in that day, and leap for joy; for, behold, your reward is great in heaven; for in the like manner did their fathers unto the prophets.—LUKE 6:23.

When, for the first time after the fire, no one could find the friend whom I have spoken about in Our Neighbors for this month, suspicion was turned upon him, and we concluded, when that part of the journal was printed, that he did it while crazed with drink. I am glad to say, however, that, some days after, we had ample evidence that he left our town on foot, and started for Cleveland Sunday *morning*. It was hard for me to believe that humanity could furnish a single specimen of such ingratitude, and I believe now that he is my friend, and would not harm me nor my property. As I mentally go over the list of those with whom I have had trouble, and weigh each one with the best judgment God has given me, I can not think of one whom I can believe it possible could commit this awful crime because of personal differences—because I had refused to give such a one work, or because I had inadvertently, directly or indirectly, injured him or his business; and yet the sad fact still stands—somebody deliberately took down the stout bar across the doorway, swung the doors open, unbuckled the head-straps to the halters, turned the horses loose, and then set fire to the hay, straw, and combustible goods stored near it, even while he felt the stiff southern breeze blowing strongly toward the long rows of seasoned lumber piles, on each side of the railway track, from the warehouse to the factory. Sin is in the world. We can not hide nor disguise the fact, that, so long as we stay here, we have got to cope with the powers of darkness; we have got to cope with human hearts where Satan has taken such full possession that not a spark of mercy or solicitude for any is left. It is a hard fact, dear friends; but, be ye not cast down nor discouraged. The Master has said, "In the world ye shall have tribulation; but be of good cheer; I have overcome the world." If, by kindness and good will, you can win men from their evil ways, rejoice and thank God; but if it all results apparently to no purpose, and if you succeed only in being hated because you are upright, there is a promise yet—"Rejoice ye in that day, and leap for joy, because of your reward in heaven."

Now a word in closing, in regard to the loss of property. If you are working for property because you expect to get happiness from it, you will have trouble and disappointment all the days of your life; and the more property you have, the more disappointment you will get. I speak from experience. If, however, property is held only in trust, and is recognized as belonging to the Master, and is used for the good of the people, and for his sake, then shall it give joy and pleasure. And now believe me when I tell you that it makes very little difference whether you have much or little, if it is held in the right way. If thousands are swept away in an hour, through no fault of your own, go on doing business carefully and economically, as if nothing had happened; save the pennies where you can save them, but let thousands slide without a murmur where you can *not* save them. Get yourself fully possessed of the idea that you are simply a faithful steward, and nothing more, and then you are all right. But be sure that the idea does not get in, that, because you *are* a steward, you are to be less earnest and zealous in caring for what God has intrusted to your care. Get selfishness out of the heart; and while you use care and economy—even such care and economy that people call you stingy, let the care and economy be for the sake of helping the people and helping the general business of the world, and not that you may make money and get rich. Labor to enrich others, rather than to enrich yourself. The incident I have given in the fore part of this paper, where Uncle Hen let his self-binder, that was *not* insured, burn up in order to save my property that *was* insured, strikes somewhat on the same point. Unless the fire company stopped the conflagration speedily, not only would I lose far beyond my insurance, but the whole community would suffer a heavy loss.

Now while I am about it, I want to say that this very trait of character, that enables one to forget self and selfish interests, is the surest way in the world to make money. It puts you where God can use you, and where he can use you for great ends. Mueller's life is something in this line. And you will remember that Jesus said, "Whosoever will save his life shall lose it; but whosoever shall lose his life for my sake and the gospel's, shall save it."

Now, please let us be careful that we make no mistake here. Some of the friends have thought us perhaps more vehement in the collection of little debts than the case demanded. If one can spare thousands in a loss by fire, why should he not forgive little debts, when people have been unlucky by sickness or bad calculations, and are unable to meet them? My friends, a true servant of God should try to do business in a way that will be most conducive to the saving of souls, and of most benefit to his fellow-men. Then the question also comes up, Does it make a man better, or does it really *help* him to let him slip out of his just obligations? I do not think it does. I have been over this ground before, through these Home Papers, and I try it over and over again in the experiences of every-day life. I have done people good a great many times, and have even helped them to come to Christ, without question, by giving them employment; but the cases are few and far between where I have conferred a lasting blessing, or have even been the means of giving any real help, by *giving money*, outright, without equivalent. It has seemed to me as if God had said, "No, no, child, don't do it;" and it is about the same where I have let people slip out of paying that which they had honestly and fairly promised to pay. Over and over again I have had reason to think it was to their hurt: therefore it seems to me it is a duty to our fellow-men, with perhaps a few exceptions, to insist that they shall do, according to promise, whatever is in their power. If they are behindhand and unfortunate, by no means crowd or distress them: give time; and if circumstances seem to indicate that it is best, let them pay interest. But to let people repeatedly slip out of meeting their just obligations, is to let them contract a disease that, like theft or intemperance, or an evil temper, sooner or later carries them down to ruin. Now, then, "seek ye first the kingdom of God, and his righteousness" in all that you do: and having done that, be not afraid of all that the powers of darkness can bring to bear. They may take away property; they may even take away life; but God's promises are sure and solid.

And fear not them which kill the body, but are not able to kill the soul; but rather fear him which is able to destroy both soul and body in hell.—MATT 10:29.

CONVENTION NOTICES.

The Southern Illinois Bee-keepers' Association will hold its third annual convention, Thursday, April 8, 1886, at 10 A. M., in Teague & Harris' Hall, Du Quoin, Perry Co., Ills. A general invitation is extended to all. F. H. KENNEDY, Sec.
Du Quoin, Ill.

The semi-annual meeting of the Western Bee-keepers' Association will be held in Kansas City, Mo., Apr. 29, 30, 1886. Those connected with the Association are desirous of making this meeting more interesting than any of its predecessors, and therefore invite all who can to be with us. It is intended to have essays read on the leading thoughts in bee culture, which will be announced as soon as arrangements are made. Let all who have bees, queens, bee-fixtures, etc., bring them if possible. Due notice will be given in regard to a hall.
Independence, Mo. P. BALDWIN, Sec.

The officers and members of the Texas State Bee-keepers' Association send fraternal greeting to the members of all other bee-keepers' associations throughout the State of Texas and all North America, and extend to them, and all interested in apiculture, a most cordial invitation to meet us at the bee-farm of Judge Wm. H. Andrews, McKinney, Collin Co., Texas, on the 5th and 6th of May. Indications for a grand meeting are growing brighter, and every effort will be made to render this the most stupendous meeting of bee-men ever held in the State. Kind treatment to all, and no hotel bills to pay. So, come one come all, as we promise you something new.
B. F. CARROLL, Sec. Texas State B. K. A.
Dresden, Texas, March 5, 1886.

The Bee-keepers of Manitowoc and adjoining counties will hold a convention at Kiel, Manitowoc County, on the 25th day of March, 1886, by the name of the "Lake-Shore Central Bee-keepers' Convention." JESSE H. ROBERTS.
School Hill, Wis., March 1, 1886.

The bee-keepers of Stark Co., met in Grange Hall, Canton, O., Mar. 2, 1886, and effected a temporary organization by electing Jacob Oswald, Pres.; J. H. Smith, of Canton, Vice-Pres., and Mark Thompson, of Canton, Sec'y. and Treas. Much interest was manifested, and we anticipate a strong organization. The bee-keepers of Stark and adjoining counties are earnestly requested to meet at Grange Hall (over Farmers' Bank), Canton, O., Tues., Apr. 13, 1886, for the purpose of effecting a permanent organization.
Canton, Ohio. MARK THOMPSON, Sec'y and Treas.

The next meeting of the Patsulgee Bee-keepers' Association will be held at Arcadia, Ala., March 20, 1886.
Raip Branch, Ala. M. G. RUSHTON, Sec.

GLEANINGS IN BEE CULTURE.

MEDINA, MAR. 15, 1886.

The Lord shall preserve thee from all evil.—PSALM 121:7.

DISCOUNTS.

NO discounts for ordering early in the season, after April 1. Until April 1, an extra 2 per cent.

BLUEBERRY-PLANTS.

WILL those who purchased the blueberry-plants from the advertisements which appeared in GLEANINGS a year ago, please report how they succeeded?

CROWDED OUT.

SEVERAL valuable articles from some of our regular contributors are this month crowded out. This is largely owing, perhaps, to the extra number of advertisements; and to meet the demand we shall put in eight extra pages in our issue for April 1.

NO DELAY IN FILLING ORDERS.

AT this date, March 17, we have caught up on every thing that was burned in our warehouse, in the way of supplies of our own manufacture; and all other goods that are burned are either here or are expected daily, so there will probably be no delay in filling any orders the friends may have had in mind to send us. One hundred thousand sections are now ahead of orders, and we expect to fill every order promptly (with a few rare exceptions), just as we have been doing for the past year and a half.

MAPLE SUGAR FOR FEEDING BEES AND OTHER PURPOSES.

WE have in stock about a ton of maple sugar, one year old, which should be worth, say, 8, 9, and 10 cts. per lb. (according to grade), if new, but in consideration of being one year old, we will sell it for 7, 8, and 9 cts. As it has been nicely kept over, it is just about equal to the new for any purpose; and the cheaper grade is as handy for bees that need stores, or stimulating, as any thing we can have. In fact, we have never had better success with any sort of feed than we have had with cakes of maple sugar placed right over the cluster. A strong colony will take care of a tin-pan cake.

LAWN-MOWERS CHEAPER.

THE little lawn-mower that pleased so much last season will now be $5.50, instead of $6.00. This cuts 10 inches wide, but we can now furnish one of the same kind, cutting 12 inches wide, for $6.00. The 10-inch one runs a little easier, of course, and it may therefore be preferable for a lady or for a child.

POULTRY-NETTING, JOB LOT.

WE have just secured some job-lot pieces of poultry-netting, which we can sell at the regular price of one cent per square foot, and you need buy only a small quantity, if that is all you want. A printed slip, giving the widths and the number of square feet in each piece, will be mailed on application. The different widths are as follows: 12, 18, 24, 30, 36, 42, 48, 60, and 72 inches. Any one who takes two or more pieces can have a discount of 5 per cent; 10 or more, 10 per cent.

MAPLE SYRUP.

A FINE article of maple syrup, such as is now made by the latest improved evaporators, is, in my opinion, one of the most delicious sweets of any thing that God has ever given his children; yes, better then any honey ever gathered, to *my* notion. We have just purchased the entire production of one of our neighbors, who has been one of the most successful and progressive maple-sugar makers. This syrup weighs 11½ lbs. to the gallon, and it is put up hot, just as it comes from the evaporator. We are now using some for our table, that is one year old, and it has apparently all the fine aroma and freshness that it had when first put up. Price $1.00 per gallon where cans can be returned, after the syrup is used out. Where we ship it so far that the cans can not be returned, the price will be $1.10, can and all. In lots of 10 cans, an even dollar each; 100 cans, $95.00. Maple syrup of former years, made in the old way, in cans holding 3½ quarts, 75 cts. each.

PEAVINE, OR MAMMOTH RED CLOVER.

MANY are inquiring as to the results obtained from this large red clover for bee-pasturage, as well as for other purposes. I believe the reports indicate that it unquestionably yields, some seasons, very large quantities of beautiful clover honey. As the honey-tubes are, however, deep, and difficult of access, bees seem to prefer to work on other sources when they can; at least, it does not seem to attract the bees every season so invariably as does alsike and white clover. As for hay and feed, it yields, unquestionably, the largest amount of any clover known; but the quality is coarse, and is not generally considered quite equal to the hay from alsike or common red clover. For turning under, however, it yields more tops and more root than any other clover known, and on this account it plays a very important part in farming operations. Our agricultural papers, almost with one assent, declare that turning under heavy crops of clover is one of the surest and cheapest ways of bringing up the fertility of the soil, or of getting manure.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

Black and hybrid queens for sale, from 15th of May during the season. Black queens until June 20th, 50c; hybrid, 75c.
J. A. BUCKLEW, Clarks, Ohio.

FOR SALE.—7 or 8 good Italian queens from a pure mother. They are mated with black drones; 50 cts. each. Address J. T. HIGHTOWER,
6 Walnut Hill, Arkansas.

FRUIT AND HONEY BEARING
TREES and PLANTS.

For $1.00 I will send by mail, postpaid, any one of the following:

- 100 *Catalpa-speciosa* Trees. As posts, they have stood 50 years, perfectly sound; good bee-tree.
- 100 Box-elder, nice shade-tree, and bees work on them early in the spring.
- 200 Golden-willow cuttings; make a beautiful tree; used for tying, etc.
- 25 Gregg Black-cap Raspberry, best variety.
- 50 Turner, a red raspberry, perfectly hardy, always bears, and equal to white clover for honey.
- 25 Snyder Blackberry, the king of berries. Never winter-kills, never fails to bear.

Send for Catalogue to RANTOUL NURSERY,
4-5-6 d. Rantoul, Ill.

LOOK ✦ HERE.

What you can get for $3.00. A 3-frame nucleus on L. frames, containing two frames of brood, Italian queen, frames covered with bees; 75 Italian queens will be sent to fill first orders. Such nuclei as I send will not only grow into strong colonies, but will doubly pay all expenses with surplus honey. A great many customers have reported over $8.00 from each nucleus. If you want full colonies, or bees in any form *except* by the pound, write me before ordering elsewhere. Orders will be filled from the 25th of May to June 15. 5tfdb

DAN WHITE, New London, Huron Co., O.

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was $40.00, but we will now sell it at half price, or $20.00.

Also one exactly like it, owned by W. W. Bliss, of Duarte, Los Angeles Co., Cal. There is nothing wrong with these mills, except that the rolls are of smaller diameter than those we now make, in consequence of which they do not make quite so thin fdn. right in the middle of the rolls as those made now with rolls of a larger diameter. They will, however, roll narrow sheets equal to any, and will roll sheets a foot wide; but when of so great a width, the center is a trifle thicker, as explained above.

Also one 9-inch Dunham mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $20.00. The list price of a new mill of this kind is $40.00.

Also two 10-inch mills of our own make, that were taken from parties who were wanting mills of longer rolls. These have been finished, and we pronounce them in every respect almost as good as new. Price $15.00 each.

Also one 10-inch mill, Olm make, fixed over so as to do about as good work as it ever did. Price $12.00. **A. I. ROOT, Medina, O.**

PURE ✱ ITALIANS ✱ EXCLUSIVELY.

STOP, ✱ READ, ✱ AND ✱ ORDER.

Having determined to devote my time and attention exclusively to the production of pure Italian bees and queens, during the season of 1886, I offer, in order to reduce stock, **50 Choice Colonies of Pure Italians** in 10 Langstroth frames, guaranteed to contain at least 4 full frames of brood and 4 lbs. of bees in new chaff hive, at $10.00 each. I append my prices for the season.

My terms are cash with the order. First orders will be filled first. I will refund money at any time a customer may become dissatisfied with waiting.

My methods: One kind, and the best of that kind. Nothing except tested queens sold at any price. I will send one-year-old queens until stock is exhausted, and then this season's hatch. I will commence to send, about May 1st.

1 tested queen	$1 00	1-frame nucleus, tested queen	$2 00
1 pound of bees	1 00	2 " " " "	3 00
1 frame of brood and bees	1 00	3 " " " "	4 00
		4 " " " "	5 00

In lots of 5, five per cent discount; in lots of 10, ten per cent discount. In lots of 10 or more nuclei or pounds of bees, I will pay express charges for the first 1000 miles. Now remember, I guarantee safe arrival and absolute satisfaction in all cases. Sample of live workers free by mail. Capacity, 25 queens per day after May 1st.

I append a few from hundreds of recommendations from last season's customers.

Sodus Point, N. Y.

I am very much pleased with the tested queen I got from you last summer. JAY S. SEELEY.

Port Dover, Ontario, Can.

I believe I can make arrangements with you for queens next spring, as what I have got from you please me very well. R. M. TAYLOR.

LATER.—*I will give you my trade for queens for 1886.* R. M. T.

Mill Point, N. Y.

Queen arrived in fine condition, and I am well pleased with both queen and bees. PETER KLINE.

Penetanquistan, Ontario, Canada.

Queen received all right, and alive. She is a noble-looking queen, and pleases me better than any I have yet received. H. T. LEACH.

BEES IN IOWA. SEE FOSTER'S ADVERTISEMENT.

DADANT'S FOUNDATION FACTORY, WHOLESALE AND RETAIL. See advertisement in another column.

FOR SALE.—One hundred Simplicity bee-hives $1.50 each. These hives are the Simplicity, except that they have a permanent bottom-board, and the cover is deep enough to allow the use of one case of 1-lb. sections, making them 1½-story hives. Nailed, and painted two coats, tin roof, 10 frames, all ready for the bees. Will be put on board here for $1.50 each. Address 7d

J. S. STARN, Freesburg, Highland Co., O.

FOR SALE.—15 hives of bees in first-class order, in Simplicity hives manufactured by A. I. Root, each having 10 brood-combs, *all worker comb;* 6 single-story and 9 two-story, each having 7 broad frames with tin separators and 56 sections. Also one Novice extractor. Will sell very cheap.

Address REV. R. MALLALIEN,
7d Green Village, Franklin Co., Pa.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED.

This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc.

Inches Wide.	No. of Rolls.	Number of Square Feet contained in each Roll Respectively.
24	3	2 rolls of 200 s. f.
26	71	22 rolls of 217, 38 of 216, 2 of 195, 2 of 215, 1 of 210 s. f.
28	11	9 rolls of 233, and 2 of 234, s. f.
34	7	5 rolls of 281 s f.
38	37	28 rolls of 316, 2 of 285, 2 of 317, 1 each of 190, 632, and 215 s. f
42	1	1 roll of 245 s f.
44	2	1 roll of 366, 1 of 348 s. f.
46	1	1 roll of 152 s f.
48	4	4 rolls of 400 s. f

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
22	1 roll 143 s. f.
24	43 rolls of 200 sq. ft. each; 1 each of 120, 168, 190, 140, 150, 140 sq. ft.
26	57 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 204 sq. ft.
28	73 rolls of 233, 11 of 224, 3 of 219, 8 of 222, sq. ft.; 1 each of 93, 245, 257, sq. ft.
30	36 rolls of 250 sq. ft.; 1 each of 235, 275, 240, 220, 227, 237, sq. ft.
32	13 of 266, 7 of 256, 2 of 253 sq. ft.; 1 each of 250, 275 sq. ft.
34	30 rolls of 283 sq. ft. each.
36	22 rolls of 300 sq. ft. each; 1 each of 288, 279, and 285 square ft.
38	1 roll each of 300 and 316 sq. ft.
40	1 roll of 233 square feet.
42	1 roll of 350 square feet.
46	1 roll of 192 square feet.

A. I. ROOT, Medina, Ohio.

JOB LOT OF POULTRY-NETTING,

At 1 ct. per sq. foot; 5 per cent off for two or more pieces; 10 per cent off for 10 or more pieces; 1½ cts. per sq. ft. when we have to cut it. Besides this job lot we keep in stock the regular 4-foot poultry-netting, in rolls of 150 lineal feet at same price as above. These figures give the number of sq. feet for each roll; and by dividing by the number of feet wide you can determine the length of each piece.

In. wide.	
12	1 piece each of 23, 50, 51, 70. and 94 sq. ft.
18	1 “ “ “ 20, 27, 54, 120, 147, and 203 sq. ft.
24	1 “ “ “ 14, 18, 24, 28, 32, 38, 40, 42, 46, 48, 52, 56, 68, 70, 84, 96, 104, 130, 160 176, 180, and 228 sq. ft.
30	1 piece each of 15, 25, 30, 37, 65, 110, 180, 194, 258, and 265 sq. ft.
36	1 “ “ “ 18, 18, 33, 33, 36, 39, 51, 51, 60, 63, 69, 69, 84, 87, 102, 111, 162, 180, 252, 258, 345, 375, 387, 390, and 414 sq. ft.
42	1 piece each of 21, 182, 200, 210, 350, and 350 sq. ft.
48	1 “ “ “ 24, 28, 32, 44, 60, 76, 80, 100, 100, 108, 116, 120, 124 140, and 400 sq. ft.
60	1 piece each of 45, 115, 125, and 180 sq. ft.
72	1 “ “ “ 24, 36, 42, 54, 54, 60, 66, 72, 72, 72, 138, 150, 186, 300, 450, and 552 sq. ft.

We know of nothing nicer or better for a trellis for creeping vines, than the above netting. The 12 to 24 inch is just the thing to train up green peas, fastening the netting to stakes by means of staples. If the stakes are set in substantially, one each 12 or 15 feet will answer. When the peas are stripped off the stakes, netting and all can be rolled up and laid away until another season. A. I. ROOT, MEDINA, OHIO.

Pure ITALIAN BEES and QUEENS

FOR SALE.

QUEENS BRED FROM IMPORTED STOCK.

BINGHAM SMOKERS

LAST AND PLEASE.

BORODINO, N. Y., Aug. 15, 1882.

All summer long it has been "which and t'other" with me and the Cyprian colony of bees I have—but at last I am *boss;* Bingham's Conqueror Smoker did it. If you want lots of smoke just at the right time, get a Conqueror Smoker of Bingham. G. M. DOOLITTLE.

INDEPENDENCE, CAL., Jan. 2, 1886.

Messrs. Bingham & Hetherington:—Dear Sirs:—

The "Doctor" came to hand last night in good order. "It is a Daisy." Won't the little pets wink their eyes when they get some of his medicine? I have one of your "Large" smokers, which has been in use six years.

Respectfully yours, WM. MUTH-RASMUSSEN.

Bingham Smokers and Knives sent per mail, postpaid, at 65 cts. to $2.00. Send for free circular to

5tfd **BINGHAM & HETHERINGTON, ABRONIA, MICH.**

CIRCULARS RECEIVED.

The following have recently sent us their price lists:

Dougherty & Wiley, Indianapolis, Ind., an 8-page list of bee-supplies.

W. H. Osborne, Chardon, O., a 12-page list of poultry.

Wm. Hoyt, Ripley, Me., 4-page list, bees and queens

Chas. D. Duval, 4-page list of bees and queens.

Frank McNay, Mauston, Wis., advertising sheet of apiarian supplies.

C. P. Bish, Petrolia, Pa., a 12-page list, hives a specialty.

A. D. D. Wood, River Junction, Mich., an 8-page list of bee-supplies.

C. M. Goodspeed, of Thorn Hill, N. Y., an 8-page club list of papers and magazines.

E. T. Jordan, Harmony, Ind., 4-page list of bees and queens.

J. W. Eckman, Richmond, Texas, 4-page list of bees and fdn.

J. J. Waldrip, Staples Store, Texas, an advertising sheet of bee-supplies.

T. S. Wallace, Clayton, Ill., a 1-page list of bees and queens.

Martin & Macy, North Manchester, Ind., an 18-page list of bees and poultry.

From Watts Bros., Murray, Pa., we get a circular of 45 pages that deserves special mention. The first 31 pages are devoted to a description of bee hive work and implements, the remaining part of the work being the price list. They give our A B C book so kind a notice that we are tempted to extract from it as follows:

"As the title indicates, it goes over the ground, from A to Z. It is fully up to the times, and is an invaluable aid to every bee-keeper. Its value is not to the mere art alone; but the author's fervid enthusiasm for the right, and his intensely practical views of religion, are so blended with the purely technical in all his writings that none can read them without being doubly benefited. The book is a mint of apicultural knowledge."

The following were printed recently at this office:

James M. Hyne, Stewartsville, Ind., a 12-page illustrated circular of bee-supplies.

Elijah Debusk, Friendship, Va., a 16 page list of apiarian implements.

A. B. Johnson, Clarkton, N. C., a 1-page sheet of bees and queens.

Jas. Erwin, Smith's Grove, Ky., a 4-page price list of bee-supplies.

CONVENTION NOTICES.

The Western N. Y. and Northern Pa. Bee-keepers' Association will hold their next annual meeting at Randolph, N. Y., May 4, 1886. A. D. JACOBS, Sec., Jamestown, N. Y.

The Progressive Bee-keepers' Association will meet in Macomb, Ill., April 9, 1886, afternoon and evening. Essays will be read, and an address given by Rev. E. L. Briggs, of Iowa. Everybody interested in bee-keeping is invited to attend.

J. G. NORTON, Sec.

The Northeastern Kentucky Bee-keepers' Meeting will be held at Covington, Ky., on Tuesday, April 6th, 1886. As the honey harvest is near at hand, it is hoped that the meeting will be well attended, for this Society has the praise of being among the best in the State. The Rev. L. L. Langstroth has been invited to attend; also C. F. Muth, G. W. Demaree, and others. ALEX. W. STITH, Sec.

The semi-annual meeting of the Progressive Bee-keepers' Association will be held at Grange Hall, Bedford, O., on Thursday, May 6, 1886, at 10 o'clock A. M.

PROGRAMME.

Address by the President, C. F. White, of Euclid.

"Bees and Fruit."—H. M. Chapman, of Collamer.

Essay by J. R. Reed, of Chester X Roads.

Subjects for discussion.—The Requisites of a Complete Hive. Which is more profitable—comb or extracted honey? and how shall we secure the largest yield of either?

There will be a "Question-box."

All interested in apiculture are requested to circulate this notice, and are cordially invited to come, bringing their lunch-baskets. MISS DEMA BENNETT, Sec.

Bedford, Cuyahoga Co., O.

Italian Queens, and 2-Frame Nuclei
A SPECIALTY.

My queens are reared from an imported mother, and in full colonies. Untested queen, in April, $1.25; in May, $1.00. Tested, in April, $2.50; in May, $2.00. Two-frame nuclei with untested queen, in light shipping-boxes (frames wired), in April, $2.75; in May, $2.50; in June, $2.25. If larger nuclei are desired add 75c for each frame wanted. Send for my circular and price list free. Address

A. B. JOHNSON,
CLARKTON, BLADEN CO., N. C.

ITALIAN QUEENS AND NUCLEI. Prices in February and March GLEANINGS.
7 9db ANNA M. BROOKS, Sorrento, Fla.

SCALE and MIRROR CARP for sale by the 100 or 1000. A fine lot of spawners now ready for shipment. 7tfdb W. L. McINTIRE, Mt. Vernon, O.

ITALIAN BEES, $6.50 per colony; five for $30.00. Queens from Hall and Hayhurst. Safe arrival and satisfaction guaranteed. E. A. GASTMAN,
7d Decatur, Illinois.

Pure Italians WITH TESTED QUEENS. I can dispose of a few colonies at fair prices. As to quality of bees, and personal character, I refer to J. E. Pond, Jr., Foxboro, Mass.
SAM'L COOMBS, FOXBORO, MASS.

EGGS FROM FANCY POULTRY.

Plymouth Rocks, 3 yards, 1, 2, 3 $. Wyandottes, 2 yards, 2, 3. Houdans, 2 yards, 2, 3. White and Brown Leghorns, 2 yards each, $ each. I have now in my yards, fowls from 5 of the best breeders in America. P. W. CORYA, M. D., Moore's Hill, Ind.
Reference, President Moore's-Hill College.

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

10 black and 10 hybrid queens for sale now. 35c for black queens, 50 for hybrid queens.

KENNEDY & LEAHY,
Higginsville, Lafayette Co., Mo.

I have over half a dozen hybrid queens for sale at 50 cts. each. Safe arrival guaranteed. Ready by April 1. S. H. COLWICK,
Norse, Bosque Co., Tex.

8 or 10 hybrid queens for sale at 65 cts. each.
G. W. BECKHAM, Pleasant Hill, S. C.

Recent Additions to the Counter Store.

FIVE-CENT COUNTER.

1 | INK POWDERS........................... ... | 40 | 3 50

Violet, green, blue, orange, black, and red. Each package will make two ounces of good ink. We are using the same in our office, and do not find it inferior to any in the market.

TEN-CENT COUNTER.

GLUE, ROYAL, mends every thing.... ... | 90 | 8 00

This is the best cement we have ever tried. Almost any article mended with it will break anywhere else before the place mended. It holds honey labels on tin, etc.

5 | CEMENT, RUBBER.................... .... | 85 | 8 00

For mending rubber boots, rubber shoes, and all kinds of rubber goods. An article worth its weight in gold, for the saving of health, annoyance and trouble. Printed directions for use accompany each box.

FIFTEEN-CENT COUNTER.

4 | INSECT-POWDER GUN......................... | 1 25 | 11 00

A beautifully finished instrument, with a neat rubber ball instead of the frail bellows commonly used. The nozzle is polished zinc, and unscrews. This will also answer for spraying house-plants, if filled with water instead of insect-powder. Neatly made, and packed in a strong pasteboard box.

A. I. ROOT, Medina, Ohio.

HONEY COLUMN.

CITY MARKETS.

CINCINNATI.—*Honey.*—There is no new feature in the market. Demand from manufacturers is exceedingly dull, while it is good for jar honey from the jobbing trade. Demand is fair for comb honey. Extracted honey brings 4@8c on arrival; and choice comb honey, 12@15c in the jobbing way.

Beeswax.—There is a good demand for beeswax, and arrivals are fair. We pay 25c per lb. for good yellow, and have paid 27c for a lot of fancy.

CHAS. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
Mar. 20, 1886. Cincinnati, Ohio.

BOSTON.—*Honey.*—No change in honey or wax.

BLAKE & RIPLEY,
Mar. 22, 1886. 57 Chatham St., Boston, Mass.

CLEVELAND.—*Honey.*—The market is unchanged since our last report. Best white 1-lb. sections are in good demand at 14c; 2 lbs., slow at 12@13. Second quality is entirely neglected. Old is slow at 8@10. Extracted, 7@8. *Beeswax*, very scarce at 25.

A. C. KENDEL,
Mar. 20, 1886. 115 Ontario St., Cleveland, Ohio.

MILWAUKEE.—*Honey.*—The supply of choice comb honey in sections is not equal to the demand, and consignments of such are wanted. We can quote:

Choice 1-lb. sections, white,	16@18
Common 1-lb. "	14@15
Dark honey, slow,	12@14
Extracted, in kegs or bbls., white,	8@9

Beeswax, wanted.

A. V. BISHOP.
March 20, 1886. 142 W. Water St., Milwaukee, Wis.

DETROIT.—*Honey.*—Best honey in 1-lb. sections, 13@14c. Stocks in commission houses are being gradually reduced. *Beeswax.*—In good demand, at 25@27.

M. H. HUNT,
March 22, 1886. Bell Branch, Mich.

CHICAGO.—*Honey.*—The market is without particular change, unless it be to a little higher range of prices for choice domestic honey in the comb, some selling up to 18 cents per lb. Extracted is dull, with large offerings, from 6@7c per lb. *Beeswax*, 22@26c; not much offered. California comb honey, 9@12c in about 60-lb. cases, 2-lb. sections.

R. A. BURNETT,
Mar. 20, 1886. 161 S. Water St., Chicago, Ill.

KANSAS CITY.—*Honey.*—Sales of comb are good, while extracted is very dull and low. One-pound sections wanted; all other grades of stocks are well supplied.

Comb, 2-lb. sections,	California,	11@12
" 2-lb. "	Eastern,	12@13
" 1-lb. "	Extra white,	14@15
" 1-lb. "	Dark,	12@13

Extracted California, in 60-lb. tin cans, 5@6c, owing to low freight. Eastern white, 5@6; Southern, 3½@4c. *Beeswax*, 23c.

CLEMONS, CLOON & CO.,
Cor. Fourth & Walnut St's,
March 23, 1886. Kansas City, Mo.

FOR SALE.—I have fourteen 22-gallon kegs of very thick dark honey, which I offer at 4c per lb., by the keg of 250 lbs., delivered at depot here. Also one keg of nice golden honey at 5c per lb. Sample sent on application. Kegs iron bound, and of best make.

M. J. HARRIS, Clay City, Clay Co., Ill.

WANTED.—Light honey in barrels or ½ barrels. Address, with sample and lowest cash price,

L. P. CHRISTIANCY & CO.,
153 Summit St., Toledo, O.

FOR SALE.—500 lbs. of well-ripened poplar and clover honey at $6.00 for keg of 100 lbs., keg thrown in. Sample by mail, 5c. CHAS. D. DUVALL,
Spencerville, Mont. Co., Md.

FOR SALE.—I have about 1300 lbs. of clover honey, warranted pure, in kegs, some 10-gallon and some 15-gallon. I will take 7c per lb. for the lot here at depot; single kegs, 7½ and 7¾ cts. Kegs thrown in.

MONT. WYRICK, Cascade, Iowa.

Wanted, Orders for Fdn.

At 45 cts. for heavy, 55 cts. for light. Wax worked. Tin Points, $1.00 per 5000. Basswood-trees 1 to 3 ft. high, $1.50 per 100; 5 to 8 ft., $4.00. Basswood seed, $1.00 per 1000, postpaid; also Wire Nails, Smokers, and Extractors. Send for Circular. 10% discount on all cash orders received before April 15th.

No. 76.

THE WINTERING PROBLEM.

A FEW weeks ago I received a call from Dr. C. M. Joslin, of Clio, Genesee Co., Mich. He has made a special study of the wintering problem, having tabulated a large number of facts concerning it. We had a very pleasant visit and discussion, and I urged him to write his views for publication. He declined, but finally agreed to send them to *me*, together with an article written by Mr. Quinby, about 12 years ago, which takes much the same view in regard to the importance of a high temperature as was advocated at the Detroit Convention. In view of the ideas that have lately been put forth upon this subject, I think Mr. Quinby's article will bear repetition. It was published in the *National Bee-Journal* for 1874, page 1 of Jan. No., and is as follows:

"I have said considerable on this subject already, but perhaps it will bear repetition. Much more ought to be said, and some things repeated, and examined in the strongest light to be found. The cause of the dreadful calamities of the past two winters should be understood as far as possible.

"A *post-mortem* investigation often discloses the *immediate* cause of a person's death. It may prove to be tubercle of the lungs, and then, unless the inquiry goes further, and finds the cause producing tubercles, but little is gained. When bee-keepers find the cause of the death of so many bees to be dysentery, it behooves them to look further, and, if possible, ascertain the cause of *that*. When we are not positive on any subject, we are apt to decide according to evidence that makes theory—or some preconceived notions of our own—probable, allowing it to take the place of direct testimony.

"Among the many investigators that have acknowledged dysentery as the cause, some few have gone further, and decided that the malady is produced by the quality of their stores—impure honey; and, to prove that honey is not healthful for them, claim that syrup of sugar, when fed, exempts from disease. Having fed the syrup quite extensively, I am pleased with the result when fed as a substitute for honey; but I have no faith in it as a preventive of dysentery, for I have fed stocks with nothing *but* that, and had them affected with it seriously. Lest some may think I mention this case to support a favorite theory of my own, I will give the statement of Mr. Elwood, of Herkimer Co., N. Y., who is a candid man, a close observer of facts, and one who has no theories of his own to bias his judgment. One year ago he fed several stocks with syrup alone, and every one had the disease as badly as those that had no syrup. These cases, even if we had no others, would show very clearly that the cause is not found in the food. It is further proved, by the case related by Mrs. Tupper, where a row of stocks that gathered their stores from the same field, each alternate one was taken and removed to a cold exposed situation, while the rest were kept warm. The first perished with dysentery, while the latter wintered well. More than 20 years ago [*now* 32 years—W. Z. H.], I became satisfied that cold weather produced dysentery. I had some stocks left on their summer stands till late in the winter, in a cold, bleak corner of the yard. Snow covered the ground. Late in Jan. they became uneasy; hundreds would leave their hives on a cold day, discharging their fæces the moment they left it. I put them into warm quarters; such as were left in the hive were quiet, and came out all right in the spring. Here is a case where they were cured of what the cold had produced.

"Food consumed by beasts generates heat, and they take it generally in proportion to the severity of the weather, to keep themselves warm. Bees seem to act on the same principle, but being, probably, natives of a warm climate, their structure is different from many animals. Being small, one alone can not generate heat enough to keep in life in a cold atmosphere. Only a compact cluster can maintain it, and then not without an abundance of food. Bees do not, when in a cold situation, seem to digest, or burn, their food, in keeping up warmth, as do the larger animals. It is exemplified when they have worked in surplus-boxes till late in the season. Take off these unfinished boxes some cool morning before the bees have all gathered into the hive, and most of them will fill themselves with honey before they can be got out of the boxes. The result is, that the honey swallowed is not digested, and warmth created, but is discharged as fæces from each as are scattered, before they regain their warm hives. When bees are very quiet in the hive in very cold weather, some must be on the outside of the cluster—I mean the cluster inside the hive between the combs, and, of course, colder than those inside. But when the weather continues cold for months, as was the case for the last two winters, those outside bees, stiffened by cold, are unable to change their position for a warmer one; their food is not digested, their bodies become swollen with fæces, and they must leave to discharge it. If the weather continues cold, the colony continues to grow smaller in proportion to the length of time and size of colony. Some colonies maintain the proper warmth by having the honey distributed so that they can have empty cells near the center, into which they can creep for mutual warmth, being more compact. Bees can exist but a short time in cold weather, when between combs of sealed honey; but they will, when properly clustered, endure any degree of cold for a time. When made warmer, don't think them safe until they are warm enough, and remain so long enough to enable them to change places with those on the inside; otherwise the result is fatal. If this is correct, it will show those who have housed their bees and lost them that they were not warm enough even then. I am aware that some will say that they have thus successfully wintered bees many times, proving to themselves beyond doubt that they were warm enough, not considering that the place that was warm enough in 1870 was not so in 1871-'2, because of the steady cold. This is proved still stronger by not finding a single case in the past two winters where the bees came out right, when only a few were housed together, unless they had the advantage of artificial heat. In discussing this subject before, I have said: 'Try the experiment of keeping them warm.' I would now say, that just this has been tried, and success has followed. M. Quinby.

"St. Johnsville, N. Y."

Dr. Joslin then comments as follows:

"While it is shown that cold is the cause of death, the best temperature is not mentioned. I will therefore quote from the ninth page of the same journal, the summing-up of the wintering of bees, by S. T. Wright, of Illinois. He says: '1. A productive queen, with bees enough to rear brood; 2. Suitable combs stored with wholesome food; 3. A pure atmosphere, of a suitable temperature, about 40° to 50° above zero being best; 4. No disturbance; total darkness and stillness being best for keeping bees quietly confined to their hives.'

"This was 12 years ago, and the problem was solved. I now come down to 1881, and quote from the pen of Geo. Grimm, as recorded in Gleanings, page 128, 1881. He says, 'Avoid late breeding in the fall; also avoid winter breeding;' to do which he keeps the temperature at 42°. Again, on page 329, Gleanings for 1881, he says: 'I repeat, leave your bees out as long as possible; they will thus consume all unsealed honey they have, and you may be assured that *all brood will have hatched*.' Another thing, and one of *more* importance, is having bees so chilled they will not again begin to breed till removed from the cellar in the spring, if the temperature is kept at 42°. Grimm's losses were 5 to 10 per cent, while H. R. Boardman's were *nothing*, and Boardman goes just the reverse; viz., encourages late breeding, also breeding in the cellar toward spring, to do which he keeps the temperature at 45° and upward. He says, if the temperature goes below 45° they take on a bad condition; 42° is not warm enough after they begin to breed, as, if lower than that, the bees have to consume too much food in keeping up the temperature. In deep wells the oxygen rises, leaving the carbonic-acid gas to settle, producing what is called 'damps,' which is death to animal life. This principle applies to all cellars or repositories where the air is undisturbed. A two-inch pipe running from the stovepipe to within two inches of the bottom of the cellar will suck up the gas and change all the air in the cellar in a few hours; but this does not regulate the temperature. I prefer the Boardman plan (see Gleanings, 1883, Oct. No.). It is good as far as it goes. I would add sub-earth ventilation, with which the temperature could be kept at about 40° until breeding begins in February, then resort to artificial heat to keep the temperature above 45°. If the weather should be very warm, raising the temperature too high, then resort to sub-earth ventilation to keep *down* the heat, which would be much better than cakes of ice or tubs of water.

"Bees do not die in summer, for they are warm enough, and have pure air. These conditions are all that is necessary to winter bees. All animal life requires pure air, and bees are no exception. When friend Hutchinson buried 57 colonies in one pit, without ventilation, the bees consumed the oxygen, leaving only carbonic-acid gas, which produced death. A little ventilation would have saved them.

"As for the pollen theory, bees never eat it when kept warm enough, hence that theory vanishes like dew before the morning sun.

"Dr. C. M. Joslin.

"Clio, Genesee Co., Mich.

"P. S.—I should like to have spoken of the temperature of 60° to 90°, and the extra amount of food eaten, the same as when too cold; of the breaking-up of the cluster to change about to eat; of the medium between the two extremes producing quiet and keeping the bees in the hive where they belong, etc., but I pause for this time. Dr. C. M. J."

There is much in the above that I should like to criticise; but the article is *now* too long, and I shall be obliged to wait until another time. I hope others will criticise the above. W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich.

A VISIT TO L. C. ROOT.

SOMETHING ABOUT THE WAY FRIEND ROOT WINTERS HIS BEES.

IN fulfillment of a long-cherished wish and purpose, I went east, after the recent Rochester bee-meeting, to Mohawk, and spent a couple of days with L. C. Root, son-in-law of the late Moses Quinby, and ex-president of the North-American Bee-Keepers' Association. Mohawk is a pretty little New-England-looking village in the valley of the Mohawk River, from which it takes its name. It must be lovely in the summer-time, embowered in trees, environed with hills, and with the beautiful stream just named flowing through it. Mr. Root lives in a neat story-and-half house on the edge both of the river and village. Needless to say, I received a warm brother bee-keeper's welcome. The family consists of Mrs. Root, two daughters, yet in the bloom of girlhood, and the widow Quinby, a bright, cheery, intelligent lady, younger looking than I expected to find her. Though a veritable member of the family, always with them at meal-times, the widow spends most of her time in a spacious parlor bedroom upstairs, the most conspicuous object in which is a large picture of her late husband, having a most life-like look, and wearing the calm, placid expression so characteristic of the original during life. I could have imagined I had seen him but yesterday, though it was in 1871 I last met him, at the Cleveland meeting of the N. A. Bee-Keepers' Association, when, though president, his native modesty impelled him to vacate the chair, and insist on its being filled by myself, as one of the vice-presidents —he felt so much more comfortable, he pleaded, sitting in a less conspicuous place. It was intended, as a memento of the love and esteem cherished for his memory by those present at the Detroit Convention, in December last, that the present to his widow, then and there got up, should take the form of a portrait of Mr. Quinby; but when I saw the one that had hung so long on the wall of the parlor bedroom I felt that it could not be superseded or displaced by any substitute. So the committee that had the matter in hand, being made aware of this, concluded to present a book. The one chosen was "Lord's Landmarks of History," a large-typed, beautifully bound work, in five volumes, I think. Mrs. Quinby prizes it much, spends considerable time in studying it, and is grateful for the tangible proof of respectful remembrance, both of her precious dead and of herself, to which it testifies. May she pass a long, quiet evening of life in the bosom of the family that loves her so well for her own sake, and for the sake of the long-since departed one, whose memory is still, and will continue to be, green and fragrant, not only in the recollection of his immediate descendants, but of all bee-keepers, whether they knew him personally, or only by his well-earned fame as one of the pioneers and apostles of modern apiculture!

Of course, my visit was chiefly for the purpose of gleaning all I could from the field of thought and experience in which Mr. Root has labored so conspicuously and honorably for many years. But bee-talks are almost unreportable, especially when the convention consists of only two members. I had the opportunity of inspecting Mr. Root's method of wintering, and the condition of his bees at that time. The close-ended frames are tied together and set on a bottom-board, having a large circular hole in the center. On top of the frames is a factory-cotton cover. The compact sets of frames are stacked one above another with considerable space between tiers, admitting of inspection from below; and it was an interesting sight to see the clusters of golden-banded insects hanging down, in some cases even with the bottom-board, or even still lower down. Then turning aside the cloth cover, it was evident that the frames were full up to the brim, indicating strong stocks. With the thermometer at 46°, the bees were very quiet—hibernating, I should say—certainly in *repose*. These colonies, about 60 in number, were in a portion of the cellar partitioned off for their exclusive use, and right under the living-room, where a base-burner coal-stove is going day and night. Beside the stove is an auger-hole through the floor, sufficiently large to admit the passage of a small round thermometer, whose records are daily noted and recorded. A number of other colonies are housed in a repository not far from the house. These we did not examine, for they were rather uneasy, and Mr. Root feared the temperature was a little too high, though not so high as Mr. Barber tells us his bee-cellars often are. Mr. Root has a couple of out-apiaries, as he considers his home field overstocked, there being over 1000 colonies within a three-mile radius. He finds the care of these out-apiaries very laborious, and questions if it pays to keep yards so far away from one's residence.

Mr. Root kindly drove me over to Frankfort, a little village about five miles distant, where lives an old friend of mine, Hon. Harris Lewis, who has for many years paid an annual visit to Canadian dairy conventions, at which his presence is greatly prized. Taking an interest in dairying as well as bee-keeping, myself, I have usually assisted at these meetings, and spent many pleasant hours with Mr. Lewis, both in public and in private. Mr. Lewis used to keep bees many years ago; and as the heathenish insects were then, as now, very apt to swarm on Sundays, he was in the habit of staying home from church to watch them. A Baptist minister in the neighborhood had commenced bee-keeping with a single hive; and since Mr. Lewis was staying home from church anyway, asked leave to bring his one hive, that they might be watched along with the rest. Leave was given, and the minister's hive stayed all summer, but did not swarm. In the fall he asked Mr. Lewis how he could get the bees out of the hive, so as to rifle it of the honey. Mr. L. told him if he would lift it off the bottom-board, and wheel it home on a wheelbarrow without any bottom, he thought the bees would all be out of it by the time he arrived. The minister came with his bottomless barrow on which the hive was quickly placed, he starting on his dubious journey, and Mr. Lewis to go indoors and roll on the floor with laughter at the mischievous joke he had played on the poor parson, who soon returned in a sorry plight, for he had not been wise enough to walk *ahead* of his vehicle. The consequence may be better imagined than described. Mr. Lewis helped him smother the bees remaining in the hive, and make a new start with the hive *minus* the bees. He owns it was a cruel trick; he would not repeat it, now that he is older, wiser, and better; but he thought then, if the minister was naughty enough to get him to watch his bees on Sunday, while he was preaching, he deserved some punishment. Mr. Lewis has lately remarried, after a long period of widowerhood. As we sat at the tea-table, he remarked that he thought he would start bee-keeping again, to which a soft and gentle voice responded, "No, you won't;" and I don't think he will.

Mr. Root is a quiet, unpretentious man, like his lamented father-in-law, but thoroughly up in bee-lore, and well maintains the family reputation in apiculture. He is a good citizen, a warm Prohibitionist, and his care in bringing up his children is evidenced by the fact that he never allows them to go to the public school, from fear that their minds might be unfavorably affected by the evil influences of undesirable schoolmates. A blackboard on the sitting-room wall, with a problem on it, gave proof of the assiduous care and pains taken in the home school. But not every family has a mother, once an effective schoolteacher, able and willing to add to househould duties the task of teaching the little ones. My visit was all too short; and, if practicable, I shall certainly accept the cordial invitation given to repeat it some time, and stay longer. WM. F. CLARKE.

Guelph, Ont., Mar. 15, 1886.

HOW TO PREVENT ROBBING.

SOME GOOD HINTS ON HOW TO TELL WHEN TO STOP EXTRACTING.

EVERY one who keeps very many bees will sometimes have some trouble from robber-bees; but considering the amount of work that we do with bees, we have had but very little robbing. We do not raise queens to sell, and do not have to open hives when there is a dearth of honey. We raise extracted honey only, and never extract when the bees will work on honey to any extent. We get the most of our honey from white clover and basswood. Clover comes first, and lasts until the basswood commences. The latter is the last from which we get any surplus. During this time we are traveling the roads every day, going to our different yards, and are passing the basswood-trees. We keep close watch of the blossoms, and can tell very nearly how long it will last, and we know that in good weather the bees will fill a full set of combs in five or six days.

Now, when the end of the season is within a week of its close we commence to leave in full combs of honey. The first day we leave in on the back side of the hive one comb full of honey. The following day we are at another yard, and we leave in two or three full combs of honey—putting them in the back side of the hive; the next day we are at another yard, and we leave three or four, or perhaps five, combs of honey. It depends on how fast the basswood is giving out. Our aim is to have the hives full of honey when the basswood flow is over. Our hives hold nine combs, and we keep on extracting until the bees begin to steal; but just as soon as the bees begin to crowd into the house we cease extracting, and our hives are by this means full of honey and brood. But when honey is coming in rapidly from basswood, the queen does not get a chance to put in much brood. The bees usually gather enough honey after the basswood is over for their present needs, but no surplus. We always guard against getting the bees to robbing. When we have to open hives out of season, we do it just before sundown.

HOW TO STOP ROBBING BY MEANS OF COLD WATER.

In this connection I will tell the best thing I ever found to stop a hive from being robbed; i. e., use cold water. I raise asparagus for market, and always have a large quantity of it in the fall. Now, if I have opened a hive and got the bees "on the steal," I cut a large armful of asparagus and bank up the hive with it. I then sprinkle on water. The asparagus holds so much water that the bees can not get into the hive, and the bees inside seem to think that it is a wet day, and they stay at home. Wet the asparagus two or three times an hour, and the job is done. If you have not the asparagus, use straw or a blanket, or something to wet the bees in their endeavors to get in. The idea is, to make the robbers crowd their way in through water. They won't do it. Try it.

HOW WE MARKET OUR HONEY.

Our home market takes about 10,000 to 15,000 lbs. We have our honey all graded as to quality. Our first extracting we retail at 8 cts. per lb.; our second extracting, about 9 cts.; best white-clover and basswood, at 10 cts.; in 100-lb. lots, one cent per lb. less. We put up considerable honey in tin pails, and sell at the above prices, with the additional cost of the pail. We keep two stores in town stocked with pails of honey—allowing them 10 per cent for selling. We give our customers the privilege of returning pails when empty, if they wish, but so far we have had but few returned. We sell from 6000 to 10,000 lbs. to the cracker-factories, who take our darkest grades, four or five barrels at a time, paying from 6 to 7 cts. We get our barrels back again from the cracker-men at Dubuque. Our old neighbors who have gone west, send back for 100-lb. kegs for their own use; the rest is sold to dealers in Iowa, Minnesota, Dakota, etc. We sell our best grades of honey at 8 cts. by the barrel of about 360 lbs.; no charge for the barrel. In 100-lb. kegs we sell for 9 cts. per lb. Last year we sold 21 barrels to Messrs. Thurber, Whyland & Co., of New York, at 8½ cts., delivered. After deducting freight and cost of barrels we had a fraction over 7 cts. for the honey. We did not send any east this year, as the demand and prices were better west. We have worked off the bulk of the crop, having on hand now about 7000 or 8000 lbs. not sold, and that will be gone by the time we get another crop. We usually keep over a few barrels, in case our bees should want feeding, as we *never feed sugar*. No, we have never fed a pound of sugar to our bees yet, and don't want to. We find it no small part of the bee-business, to work off so much honey and obtain good prices and get our pay for the honey. Last year we got caught on 12 barrels of honey, amounting to $345.60, sold to Geo. W. House, of Manlius, Onondaga Co., N. Y. The honey was shipped Nov. 6, 1884. Dec. 9, I received his note by mail for the amount, due in a month. Time passed, no pay. I wrote to him; no answer. I wrote three or four letters. Once he replied, "Pay soon." I made inquires about him, and found it was a bad job. He has never paid a cent. I have his note for $345.60, for sale cheap. Who bids?

Now I should like to ask our large honey-producers how they manage to get good prices for their honey, and never meet with losses. Is there any sure way to find out on short notice if a man is reliable and honest? E. FRANCE.

Platteville, Wis., Mar., 1886.

Friend F., you have given us just the information wanted. See page 276. Your honey, then, nets you, even in your largest lots, not less than 7 cts.—I am surprised and greatly pained to find that you have been made a victim of George W. House. For more than a year I have been telling him we should have to publish him if he didn't stop purchasing honey for which he didn't pay. It is a very difficult matter for an editor to decide how far he should bear with a man of this kind before warning the bee-friends against him. Mr. House purchased honey in the same way from several other bee-friends, including Mr. Chalon Fowls, of Oberlin, Ohio. His plan is to give his note, when his note is good for nothing. He has obtained more credit, from the fact that he has been a prominent writer, and a prominent worker at bee-conventions. You did exactly the right thing, friend F., in giving the whole transaction, and I hope no one will trust him again after this public exposure. You ask if there is any way to find out on short notice. It is a little difficult with bee-keepers, as they are not quoted in our commercial reports as men who are in mercantile or manufacturing business. You can do this, friend F.: Drop a postal card to us; or, if the case is urgent, telegraph. Had you sent us a telegram before you shipped that honey, we would have wired you back instantly, "Under no circumstances trust the party a copper." Mr. H. has been making promises all along to settle up all these matters; but I had no idea that he had purchased from any one any such sum as you mention.

FIFTEEN TONS OF HONEY.

HOW FRIEND COGGSHALL MANAGES.

FRIEND ROOT:—Mr. E. France, page 122, gives you his method of handling apiaries away from home. I have four apiaries. One is ten miles away, the others are two or two and three miles respectively. For this purpose I usually lease plats of ground for three years, and hire the man who lives there to hive the swarms. Let me say, here, that fifty or sixty colonies in one location will gather more honey than 200 colonies, year in and year out.

I advocate mixed farming, and extracted and box honey in the same yard. There are always some colonies that will not work in the boxes readily, and some that are not strong enough. What extracted honey I get from these is clear gain, and they are the better for it, as it gives the queen a chance to lay. A good way to keep the queen below is to lay thin pieces of boards over the frames, say 3 pieces 5 inches wide on a Langstroth hive. I would put them close together at the back end of the hive. This helps, also, to keep honey below for winter stores.

I hired my help by the day for about a month last year, except those I hired to hive the swarms. These latter did not take off any honey. I had over 22,000 lbs. of extracted and 8000 lbs. of box honey. One day, with the help of a man and a boy in the forenoon, and a man and myself in the afternoon, I took 3100 lbs. of extracted honey.

For a honey-house I have a building 12×16 and 8 feet high, boarded up and battened, with shingle roof, and with matched flooring. Such a building can be put up for $30, made out of hemlock lumber, with third-class shingles. I have the door where I carry in the honey, on a level with the ground surface, so I do not have to step up when I am carrying in a load of honey.

I always have a stationary extractor arranged so I can draw the honey at any time; also a can for the storage of extracted honey, with a faucet, and set high enough to run under a barrel. A cheese cloth, fastened on a hoop, fits the storing can. This strainer can be taken and rinsed in two minutes. I use, also, a strainer, or cullender, made out of a tin pan set on a tin bucket, and placed high enough so I do not have to stoop to work. I have a place arranged to set the combs just as high as the extractor, and as close as possible to the extractor. Each barrel, as it is filled, should be marked with the grade, when it is rolled away from the storing-can, and a wire gauze nailed over the hole. I always fill from the head, and I usually leave the honey in the honey-house until I draw to the depot. In the winter I get oak barrels that hold 350 lbs., and wax them by taking out the head, and, with a swab, I wax every seam or joint. I use rosin, two parts, wax and tallow one part. The whole secret is to have every thing ready.

I see Mr. France has a boy to carry three combs in each hand. He should have a carrying-box, so a boy could carry 8 or 12 combs. He then could accomplish as much again work in the same time. Here I am telling how other people ought to do. I intended to tell how I did.

MY STOVEPIPE SMOKER.

The smoker that I use is a stovepipe, 7 in. long, with a bottom in; a hole cut in the side with a slide to shut it off; a hook on one side, and a handle riveted on 6 or 8 inches long. Hang the smoker as thus constructed on the windward side of the hive, with some fire and chips in it. The beauty of it is, you can burn any thing, and you do not have to keep blowing it.

I bought some of your brushes; they did not answer my purpose, so I got some fine broom-corn brushes, made 9 in. wide at the brush end. I have a loop cord on it, and put it around the neck. Let it rest on the left shoulder, and allow the brush to hang by the right hand. It is always at hand wherever you are, and you do not have to stoop to pick it up. It is wide enough to clean a Langstroth frame of bees at one or two sweeps of the brush.

I will say to those who contemplate adopting the reversible hive and frames, Go slow.

18—W. L. COGGSHALL, 220—400.

West Groton, N. Y., Mar. 4, 1886.

Thanks, friend C. Facts like the above, from practical honey-producers, are what we want. I would put in a caution, however, against the use of rosin. Years ago we decided that any admixture of rosin with beeswax would, in time, give the honey a slightly resinous flavor. — Your stovepipe smoker is pretty nearly the Townley smoker, described in the A B C book.

A SWARMING-BOX TO HOLD A FRAME OF BROOD.

FRIEND KALER'S DESCRIPTION OF IT.

THE friend mentioned below has made a box for taking down swarms, arranged so as to hold a frame of unsealed brood, taking advantage of the well-known disposition of bees to cluster around and adhere to such a comb. The cut below, and description, will make it all plain.

DESCRIPTION OF CUT.

A is a swarming-box made to hold a frame of comb; made perforated.

B, rests that hold the swarming-box in place. It also contains slots to receive the handle.

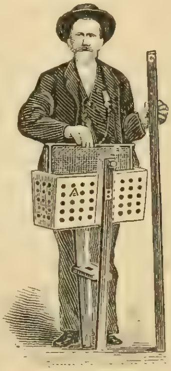
C, the handle of different lengths, to raise the box to a proper height.

D, a frame of comb to place in the swarming-box for bees to *cluster on.*

DIRECTIONS FOR USING KALER'S SWARMING-BOX.

Get your box clean; take from the hive that the swarm came from (if you like), or some other, a nice frame of comb. Place it in the box. swing the box in the rests. Then select a handle to raise the box just under the swarm. When ready, jar the bees into the box. In a few minutes they will be all clustered on the comb in the box. If you are not ready to hive them, or another swarm comes off before you are ready to hive the first one, remove the box from the rests and set it away in the shade, being careful to cover up snugly. Place another box in the rests, and proceed as in the first case. After they are all in the swarming-box they are almost as safe as in the old hive. Now, when you are ready to hive them (but do not be in a hurry), get things ready and remove the frame from the box gently, and place it in the hive. Cover up the hive, having every thing in shape. Shake the remainder of the bees from the box, in front of the hive. Watch a moment, and see that they start in, and it is done. W. S. KALER.

Andersonville, Ind., Jan. 28, 1886.



KALER'S SWARMING BOX.

GOOD REPORT FROM A LADY.

FROM 24 TO 48, AND 2820 LBS. OF HONEY; THE PROCEEDS OF ONE COLONY, 279 LBS.

I DO not know that I read any part of the varied matter in GLEANINGS with more interest than I do the reports from different bee-keepers in different localities. When we have had almost a failure, the old adge, "Misery likes company," proves true. In giving our report for the season of 1885, it might be well enough to explain that my position is only that of "general assistant in the apiary." The principal members of the firm are Rev. J. S. Woodburn and W. M. Dougherty (the latter being my only brother). In the spring we lost five or six, and sold five, leaving us about 24 to begin the season with. We raise mostly extracted honey, and by the 24th of June we found the combs full and capped completely. We took 925 lbs., gathered from the poplar-blossoms. I have been watching in GLEANINGS to see if anybody else had poplar honey. It is dark, thick, sticky, and very sweet. Our children like it on their buckwheat cakes, but it is not salable, even at a reduced price. On the 22d of July we took 1337 lbs. of beautiful basswood honey, well sealed over. In September we took 501 lbs. of buckwheat honey, which, with 100 lbs. of comb, made 2820 lbs. for our season's work, besides leaving the bees an abundance to winter on. I think our bees had access to nearly 100 acres of buckwheat, some of it quite close to them. By the way, how much buckwheat did your acre yield? Ours yielded about 24 bushels to the acre. One colony of bees gave 224 lbs. of honey; it was a pure Italian. Another, a Holy Land, gave 174 lbs., and threw off a swarm June 1st, which gave 105 lbs., making in all 279 lbs., the largest yield in the apiary. I neglected to say, in giving the amount of honey taken, that we also increased, by natural swarming and dividing, up to 48, which number is living yet. Some of them had a fly to-day.

MRS. BELL L. DUNCAN.

Black Lick, Pa., Feb. 8, 1886.

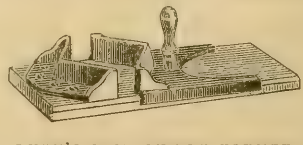
Our buckwheat yielded pretty close on to 40 bushels per acre. Thanks for your excellent report from the Holy Lands, my friend.

AN IRON SECTION-BOX FORMER.

SOMETHING THAT SEEMS TO BE A HELP, EVEN IF IT IS A LITTLE "MACHINERY."

SOME time in February friend G. R. Lyon of Greene, N. Y., sent us a section-box former shown in the cut below.

The machine is made of two heavy pieces of cast iron, arranged so as to slide easily upon a board. Pushed up together they inclose a square space a little smaller than a Simplicity section box; therefore, when with your fingers you quickly stick a box together, either one-piece or four-piece sections, drop it in the former, then, sliding up the movable piece of iron by means of the handle, every corner is pushed up smooth, and no further.



LYON'S SECTION-BOX FORMER.

The corners all come up, and also come out of the former perfectly square, ready to have the starter inserted, when it may be placed directly in the wide frames or in the cases. Where you drive them together with a mallet, they may be square, and they may not; besides, the mallet frequently drives the pieces in too far, where the grooving-saws have cut a little deeper than they ought to do. What looks more awkward than a neat basswood section box, nicely filled with honey, but out of square, because the owner failed to give it to the bees square and true? It seems to me that this instrument ought to have a large sale, even if friend Lyon has, perhaps, got the price a trifle high. He sells them at $1.00 each; one-fourth off where 50 or 100 are purchased at a time.

DOES THE QUEEN LAY DRONE OR WORKER EGGS AT PLEASURE?

FACTS TO PROVE THAT SHE DOES.

IN Mr. Dadant's article on page 95 of GLEANINGS for Feb. 1, he expresses his belief that the external conditions present at the time of the laying of the eggs by the queen determine the sex of the bee to be produced. I have reasons for thinking differently from Mr. Dadant. The queen will lay in worker-cells of foundation before it has been worked out enough to compress the spermatheca in the least, and these eggs will produce workers, and must have been fecundated by the volition of the queen. The queen will also lay eggs in queen-cells, as stated by Cook, which are larger than drone-cells; these eggs, hatching queens, must also have been fecundated by some other process than compression by the cell.

Another evidence, to me, that the laying of fecundated and unfecundated eggs is not automatic with the queen is this: In the fore part of the honey season, when the colony begins to thrive, and commences to make preparations for swarming, the queen will skip over considerable worker-comb to get to the drone-comb, and will fill it with eggs almost invariably. In the well-regulated apiary, but little drone-comb is to be found; therefore the comb-builders will build drone-comb wherever they can, even on the ends of frames; and under the above conditions, if you insert a frame containing both drone and worker comb, the drone comb will invariably be filled with eggs first.

Now, if egg-laying, or, rather, impregnating the egg, were done entirely without the will of the queen, and by the compression and non-compression of the spermatheca, why does she lay in the drone-cells first? And, vice versa, later in the season, when conditions in the hive are reversed, and the honey-flow has almost ceased, it is almost impossible to get a queen to lay eggs in drone-comb without feeding, when the colony is in a normal condition.

Mr. Dadant says that he has replaced drone-comb with worker-comb in the brood-chamber, and the queen did not seem dissatisfied with it; and he says, "If the queens, while laying, were moved by the desire to lay drones (eggs), our replacing of drone-comb by worker-cells would be useless." I suppose by this, he thinks she would show her dissatisfaction by laying unfecundated, or drone-eggs, in worker-cells; but this would be "against the rules," and not natural, and not for the good of the colony; and her laying the eggs in the proper cells indicates to me that she knows what she is about, and lays her fecundated and unfecundated eggs in the proper cells, where they ought to be, and where they will hatch out the proper occupants for the cells they occupy. I think the colony and queen do show their dissatisfaction when we replace a worker-comb to the exclusion of all drone-comb. They build drone-cells in every conceivable place they can find, and it is always filled with eggs as soon as it is built, at a certain time of the honey season; and some writers assert that they even remodel worker-foundation and build drone-cells upon it; and queens frequently go into the surplus-boxes and deposit eggs if there is drone-comb to be found there, and there is none or very little in the brood-chamber. Drone-foundation has been condemned for surplus-boxes, partly, at least, on this account.

In the last paragraph of Mr. D.'s article he suggests that the reason the cells of the wasp are not all filled alike may be on account of her inability to obtain spiders enough at the time to fill all of them alike. This may be so; but suppose that spiders happened to be very abundant, and she could fill them all as full as she does those for the females, in which case, according to Mr. D.'s theory, she would lay none but female eggs, and produce no males. This would hardly be according to nature. Also, if I am not mistaken, Sir John Lubbock says that a wasp always takes the same number of spiders. This would also go against Mr. D.'s theory, and would show that she did not provision her cells in proportion to her success in hunting, but with special reference to their needs, both male and female.

Mr. D. also says: "When the eggs of animals are mature they don't wait, but drop." I think this is not so in regard to queen-bees; for a queen taken from a populous colony, when she is laying, perhaps one or two thousand eggs per day, will stop off short, if she has no comb to lay in; and in case of the wasp, suppose the weather were very unpropitious, and spiders were very scarce, and she could get none, she would have to lay in an empty cell if she were obliged to "drop," as Mr. D. says.

I have not seen evidence enough yet to convince me that the laying of eggs by the queen is automatic, in the sense spoken of in Prof. Cook's and Mr. Dadant's articles. EDWARD B. BEEBEE.

Oneida, N. Y.

THE AUTOMATIC EXTRACTOR.

SOME HINTS IN REGARD TO USE OF.

YOUR description of the Automatic honey-extractor, as shown on page 52 of GLEANINGS for Jan. 15, is very good, but you make a very common mistake in your plan of operating the machine. Instead of starting with a "quick impulse," you should start very gently either way, and turn about one-half way round; then stop and gently but firmly start the reel in the opposite direction, and the impetus given to the comb-baskets will carry them off the vertical center, and they will pass out to their several positions. You may now increase the speed as desired; but if the combs are very heavy, do not turn too fast, but give just enough motion to throw out a part of the honey. To reverse, stop the motion and let the baskets swing clear by the center and nearly to their position, "t'other side out," and then gently start the reel the opposite direction, and the combs will take their new position without even a jar. You may now give sufficient speed to throw all of the honey from this side, and then reverse as before, and finish the side first extracted from. If the combs are very heavy or very tender, it may be well to reverse three or four times, while, if the combs are strong and the honey is new, once reversing will be sufficient. If there should be any brood in the combs, great care must be taken not to dislodge it; but if no brood is present, you can let the thing hum, and 60 seconds is time enough in which to place, extract, and remove four of the heaviest combs; and if this is not fast enough, you must get a machine with more baskets. If you will follow the above directions you may fill the baskets in the morning with hens' eggs, and reverse them all day without cracking a shell.

Your plan of starting a branch supply-house at the South, I think, is an excellent one, as it will be a great saving of freight and express charges to your customers, in that section. We have also started a factory to accommodate our friends who want extractors at the far West and Southwest. The new works are located at Topeka, Kansas, and are carried on by J. E. Stanley, my brother, who has been, for the past five years, in company with me. G. W. STANLEY.

Wyoming, N. Y.

HOW TO CHANGE HYBRIDS TO PURE ITALIANS.

ALSO SOMETHING ABOUT FEEDING CHEAP FOOD TO FILL THE BROOD-DEPARTMENT JUST BEFORE THE HONEY SEASON OPENS.

I HAVE five swarms of pure Italians, and nine swarms of hybrids and blacks. I wish to raise queens from my Italians, and Italianize all my hybrids and blacks, this spring, before they can raise drones to mate with their young queens. I am sick of the hybrids and blacks. Now, what is my best and surest way to do it?

When granulated sugar can be bought for 8 cts. per lb., and comb honey can be sold for 11 to 13 cts. per lb., will it not pay to feed bees enough sugar syrup for breeding purposes, and to fill the brood-combs, so that what honey they gather may be stored in the sections or boxes?

I mail you, in a small box, a small vial containing a sample of sorghum, which cost me 15 cts. per gal. How would it do to feed bees with, after the weather gets warm enough so that they fly nearly every day? W. H. C.

Bucklin, Mo., Feb. 27, 1886.

Friend C., if you have no black bees in your vicinity, the matter can be very easily managed. Encourage the production of drones in your hybrids and full-blood colonies by every means in your power, such as stimulative feeding, and put drone-comb in the center of the brood-nest, before the black bees will ordinarily want it to start drones. Then cut out all drone-brood from your blacks as soon as it appears. Now raise young queens from your best Italian stocks, and there will be a great probability that they will be purely mated; yes, even if there are black bees in your neighborhood. As soon as you find, by their progeny, they are purely mated, well and good; if not, discard them, and so on.—If your bees are lacking in stores, and do not get all they need from fruit-bloom, it will most assuredly pay you to fill up the brood-apartment pretty well just before honey begins to come in. For this kind of spring feeding you can take any kind of food the bees will carry into their hives. Your sorghum syrup is just as good to raise brood as granulated sugar; and perhaps better, if the bees will take it, and they generally will in the spring, when they can fly. Of course, if you value your reputation as a honey-producer, you want to be very sure that not a drop of this goes into the sections. I do not think it will be a very difficult matter to manage this.

HOUSE APIARIES, AND THE WINTERING PROBLEM.

OLIVER FOSTER'S 14-HIVE HOUSE-APIARY.

ON page 178, March 1, friend Wm. F. Clarke asks for the republication of my description of a house-apiary as given in May, 1882. In his foot-notes to friend Clarke's article, the editor says: "Before republishing the article, we should like to have him tell us how it answers by this time."

After the added experience of four years, I can say that there are important advantages in the house-apiary referred to. In fact, I am more firmly decided than ever that the fundamental principles of the most successful system of management are comprehended in the main features of this plan. You remember that I "set my foot down" on this point at the time, and it is there as flat as ever today. While nearly all hands and minds of the bee-fraternity have been at work on the wintering problem, bringing about important developments on the line of cellars and sub-earth ventilators, a considerable proportion of my time, money, and midnight meditations have been expended in the effort to avoid the disadvantages, and appropriate the advantages, of the 14-hive house-apiary, with special reference to the wintering problem.

I have each year added improvements; each winter I have tested the new plan as far as developed, with nearly my whole number of colonies, but never following the same plan any two years. After these numerous modifications, the careless observer might not recognize in my present appliances and methods the original house-apiary; but the important principles are all there.

1. Economy of ground room in the apiary.
2. Economy of steps in handling.
3. Economy of chaff in packing.
4. And, most important, economy of the heat of the bees by bringing the colonies so close together that they keep each other warm. But,

WHY ECONOMIZE HEAT

so carefully while we hear of so many colonies dying from being "packed up too warm"?

Beg pardon, but I don't believe bees were ever packed too warm, if they had plenty of *fresh air;* and it is to enable us to give this air that we wish to economize heat as far as possible. If you will present your nose at the entrance of one of these closely packed colonies I think you will be convinced that something more than heat and moisture is escaping.

The fact, that from five to ten pounds of honey (but a small per cent of which is water) passes off through the air from a colony during winter confinement, tells the same story.

Does the science of ventilating a bee-hive differ so much, after all, from that of ventilating public buildings? In scientific discussions on the ventilation of buildings we do not hear very much about the injurious effects of moisture. We do not find the attics of our churches and schoolhouses packed with "absorbing materials." They tell us that poisonous impurities, carbonic acid, etc., are constantly being thrown into the air from every breathing thing, and that these poisons cause certain death to man, beast, or insect, unless carried away by the air.

We would not underestimate the importance of complying with all the conditions necessary for reducing to the minimum the accumulation of this refuse matter, which seems to be the objective point of most efforts at present. But I think the lack of ventilation is a potent cause of over-consumption of stores, and consequent accumulation of fecal matter.

We have also reason to believe that, with perfect ventilation and a high temperature in the hive, which can be combined only by the house-apiary principle, a large per cent of the refuse matter will be discharged through the air that would otherwise clog the intestines. There are objections to the house-apiary as described in the article referred to. It takes an odd-sized frame, which is intolerable. The hives are immovable, and it is difficult to get all the bees out of a hive when desired. The bees and queen are liable to get into the wrong hive. The house has no floor, only the ground. As for bees getting out in the house, I do not consider that an objection, as I have had no such trouble. I would hardly advise any one now to build a house *just* like this.

The details of just what I would advise I will reserve until I have had a little more experience.

Before closing I wish to thank you kindly, Mr. Editor, for your kind words on page 90, and elsewhere, from time to time. Such recognitions are incentives to improvement.

10—OLIVER FOSTER, 250—296.

Mt. Vernon, Iowa, Mar. 4, 1886.

THE SOLAR WAX-EXTRACTOR, AND HOW TO MAKE IT.

FRIEND GREEN GIVES DIRECTIONS FOR ARRANGING ONE IN A SIMPLICITY HIVE.

YOU seem to be the natural friend of the small bee-keeper. Now, you can furnish this class with solar wax-extractors at a very moderate price. Most of your disciples have the Simplicity hive. To transform this into a wax-extractor, make a sash for glass that will fit on the top of a Simplicity. You can furnish these sashes either with or without glass. Furnish with them a sheet of perforated metal about 13 x 17, and a sheet of tin 14¼ x 18½; also, if you like, a dripping-pan about 13 x 17.

The buyer of one of these outfits has only to place a Simplicity hive on a tight bottom-board; place the pan inside, blocking it up until its top is about three inches below the top of the hive; lay the sheet of perforated metal on this; put on the sash; put the sheet of tin in the cover for a reflector; hinge hive, sash, and cover together temporarily, and he has a wax-extractor which can be turned back into a hive at any time when so desired. On hot days no reflector will be needed, so that all it would be really necessary to buy would be the sash and sheet of perforated metal—any pan that will go inside of a hive answering the purpose.

I have no doubt that, if you will get up outfits of this kind, you will sell hundreds of them, make bee-keepers happy, and make a good thing out of it yourself. I would go into the business myself, only, as I said before, it would be useless to compete with your facilities. Even if I could make them as well and cheaply as you could, you could sell a great many more than I could, do more good, and make more money.

In use it is to be placed on the south side of a building, and the cover leaned against it at the proper angle. If much wax is to be melted, time will be saved by turning it a little, several times a day, so as to face the sun; also that, if any one wants to run the honey and wax into the honey-house, all he will have to do is to bore a hole through the corner of the case and run a trough from the tube in the tin pan, through into a receptacle in the honey-house. Where there is much honey in the comb to be melted, as where a large quantity of cappings is to be rendered, this is the better way, as the honey becomes overheated and injured by being left in the extractor long.

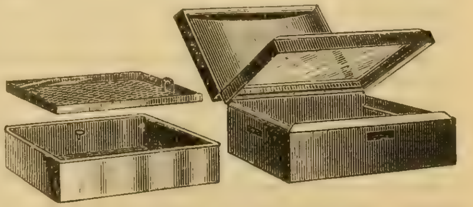
In regard to the use of a double-glass covering, some seem to think that its purpose is to "draw," "gather," or "attract" the heat of the sun, just as some persons say that a piece of metal or any thing of a dark color "draws the sun." This language, of course, is erroneous. A double glass attracts no more of the sun's rays than a single glass or no glass at all. The purpose of the double glass is to prevent the escape of the heat that is within the extractor.

It is a curious fact, that glass, while permitting *luminous* heat-rays, such as those in sunlight, to pass through it quite freely, is almost impervious to rays of heat radiating from any *dark* source. The radiant heat of the sun, passing through the glass of the solar extractor, is absorbed by the beeswax, and changed into sensible heat, in which form it can not escape by radiation the way it got in. It might be carried out by conduction, but glass is a very poor conductor. Dry air is one of the poorest of conductors. A sheet of dry air, inclosed between two sheets of glass, forms a very perfect non-conductor. We might compare this arrangement to some kinds of traps. The heat of the sun finds its way in easily enough, but it can not get out again. A single sheet of glass will conduct the heat off a great deal more readily than two. In very hot weather I have made beeswax simply by placing the comb on a sloping board in the sun, without the aid of glass to confine the heat or reflectors to increase it, so I have no hesitation in saying that a single sheet of glass will do very well during most of the summer. A double-glass extractor, though, will melt wax faster, ordinarily, thus having a greater capacity, and it can be used at many times when a single-glass extractor would not work.

J. A. GREEN.

Dayton, Ill., Feb. 9, 1886.

After the wax-extractor sent us by friend Green was received and tested, we turned it over to the foreman of our saw-room, and he shortly gave us one as shown in the drawing below.



SOLAR WAX-EXTRACTOR AS DEVISED BY FRIEND GREEN.

This wax-extractor is made exactly the size of the Simplicity hive. A pane of glass is let into the rim, exactly like the rim that goes around an ordinary cover. This is hinged to the body of the machine. Another lid is also hinged to the one containing the glass. This latter is simply a Simplicity hive-cover, with a sheet of bright tin pushed into the inside. At the left of the engraving a tin tray is shown. This tin tray has a tube at the corner to carry off the melted wax. A pipe may be connected with it to run the melted wax into the inside of a building, if you wish. Inside of this tin tray is a shallower one, made of perforated zinc. This is to contain the bits of comb. A handle is attached to each end, for convenience in lifting it out, and it is prevented from going clear down inside of the tin tray by bits of tin. Now, then, how low can these machines be furnished? We can furnish them, all complete for shipment, for $3.00; or with the above directions you can probably make one.

SUB-EARTH VENTILATION.

A DISCOURSE IN REGARD TO VENTILATING LARGE BEE-CELLARS.

IF I were planning a perfect cellar for wintering bees, I think I would have it perfectly air-tight, except one place for the entrance of fresh air, and another for the exit of foul air, meaning, by "foul air," that which is not quite so pure as the open air. The air that entered should come through an underground passage, so deep and so long that the temperature would be just right for the bees, making allowance, if necessary, for the air being somewhat cooled by the cellar walls and ceiling. It should be capable of being kept perfectly dark. Now let us see what the difficulties are in the way of securing this ideal cellar, and how, if possible, we may overcome them. Suppose in our imaginary cellar we make a small hole in one wall. Will air pass in or out through this hole? If there be a large pipe to bring in air, and a small shaft to carry it out, then air will pass *out* of the hole in the wall. If, on the other hand, the entrance-pipe be small, and the exit-shaft large, then the air will pass *in* at the hole in the wall. If there be a number of such holes, in the latter case air will pass in them all. Precisely this condition exists in my house cellar. There are three six-inch stovepipes for the exit of air, and one four inch tube for entrance, being a provision for the exit of at least seven times as much air as can enter the entrance-tube. The result is, that instead of all the air coming in through the underground tube at 40° above zero, a large part, and probably much the larger part, comes in through the various cracks about the cellar, at a temperature varying with the weather, ranging from 40° above to sometimes nearly 40° below. As a result, I keep two coal fires constantly running to warm up this cold air. To make matters better, I must just reverse the present state of affairs, and have enough air come in through the sub-earth tube to balance all that can pass out through the exit-pipes and the cracks in the wall as well. I might close one or two of the exit-pipes, but I want to be sure of enough ventilation for the 216 colonies. A friend at my elbow suggests that I might stop the cracks in the wall; but to make an air-tight cellar is exceedingly difficult, if not impossible.

Thus far, I know my ground tolerably well; but now I begin to grope, and my only excuse for going on is, that I am anxious to find out from others just what I ought to do, and perhaps I can best do so by stating some points which I think I know, and making guesses at what I don't know.

As data, I give the following from a card of the Joliet Mound Co., of Joliet, Ill. The first column gives size of tile in inches, inside diameter; the second, the number of gallons of water it will carry per minute, at a grade of 3 ft. fall per 100 ft.; and the third, the price at the factory per 100 ft.

4	163	$1.50
6	459	2.50
8	923	4.00
10	1613	6.00

This table showed me how far I might get wrong by mere theory, for I had figured that the carrying capacity would be as the squares of the diameters, making the 8-inch tile carry four times as much as the 4-inch, but it will be seen that it is nearly six times. This makes me a little chary about theorizing about any part of it, and I should very much like to ask some one who *knows*, just what I need to do, to ventilate and warm by a sub-earth pipe, this 31×33-foot cellar. In thinking the matter over, it occurred to me that by using larger tile, and partly stopping the entrance, a much shorter tube would admit air at a given temperature, than by using the smaller tile. To find out how much difference stopping would make, I went down cellar and closed the entrance of my four-inch tube about one-half, first having taken the temperature with it fully open. After leaving the thermometer in it for half an hour, I found, very much to my surprise, that the rise was so little that I could not detect it with a common thermometer. I then replaced the thermometer in the tube, and plugged the tube up tight, and left it four or five hours. On taking it out, it was not so much as one degree higher than when the tube was wide open. So I learned little about the effect of partly closing tubes; but I did learn that, practically, 100 feet was as long as there was any use in having my four-inch pipe; also, that, at the depth it is laid (the man who dug it has just told me it was fully 4 feet deep), I can not expect to bring in air warmer than 44° at the beginning of winter, and 36° toward its close, always allowing for inaccuracy of thermometers. (Bro. Root, why don't you sell *tested* thermometers, even if they do cost more?) Here is one difficulty: The sub-earth air is colder in the latter part of winter, than at the first, and it ought to be just the other way, ought it not? I don't see how we can get over this difficulty. I suppose at this distance from the factory, tile will cost much more. My four-inch tile cost more than double; and in making any estimate we might figure on double prices. The cost of laying the tile varies, of course, with the ground to be dug. I think it cost me about 50 cents per rod, or 3 cents per foot. It is clear, that the tile should be laid deeper than 4 feet. I wonder how deep it should be laid to bring in air at 45° in the latter part of winter. I'm afraid it would have to be 5 or 6 feet deep, making the work cost perhaps 5 cents per foot. Doubling the price of tile as found in the list, this would make a four-inch tube cost per foot, for tile and work, 8 cents; an eight-inch tube 13 cts., and a ten-inch tube 17 cts. As an eight-inch tube carries six times as much as a four-inch tube, suppose we close the entrance of the eight-inch tube to about one-third its full size. That will allow twice as much air to pass as the four-inch tube will carry; but as the inner surface of the eight-inch tube is double that of the four-inch, it has double the warming capacity; so with each tube 100 feet long. A double amount of air may be brought in at the same temperature through the eight-inch tube. It would be cheaper to lay one eight-inch tube at 13 cts. per ft., than to lay two four-inch tubes at 16 cts. Possibly, however, the two smaller drains might be the cheaper; but the larger one would have this decided advantage, that a large quantity of air could be flushed into the cellar at any time, even if not up to the desired temperature.

How would this plan do? Use large tile, perhaps ten-inch, laid so deep and so long that, at the beginning of winter, it would admit air about the right temperature; then every three or four weeks, as the ground became colder, close up more and more the entrance, thus keeping up or raising the temperature. Perhaps I have done enough loose guessing, and I shall be glad to be called to order by any one who will show where I am wrong, and at the same time show us what is right.

Referring to your remarks, Bro. Root, on page 169, I don't think it would be well to add any dampness to my cellar. I hardly see, either, the advantage of a heated reservoir. Would it not cost as much to heat the reservoir, as to heat the cellar direct? My three stoves will cost, in all, about $16 for the winter. I fill them each morning and evening, and that is all the attention they have. C. C. Miller.

Marengo, Ill., March 2, 1886.

Friend M., I am glad to see that you have gone into this matter so thoroughly. The rate at which the air passes through the sub-earth ventilator, I think, will have much to do with its temperature when it reaches the cellar. If a stiff breeze should pass through the four-inch tile when the air outside is below zero, it seems to me it could not be warmed, say 40°, in passing only 100 feet. The earth would be gradually frozen around the tile, commencing at the outer end. Of course, the depth would make a difference. Well, closing the opening in its inner end would, of course, make the current of air pass slower, and this might be graduated, probably, so that the ground would take the frost out of the air as fast as it passes through. In that case the temperature should not keep getting lower until the latter part of the winter. I think a large-sizeed pipe will be cheaper and better. The air from my underground reservoirs is quite warm and comfortable, even when the temperature is below zero outside. Now, when tile-factories are a good way off, and with thin flat stones easy of access, can not an underground passage be made with stones cheaper than with tile, and so as to carry in and warm a large volume of air? It seems to me there is not a question but that the heat of the earth may be so utilized as to warm buildings sufficiently to prove a very great saving of fuel. Since my warehouse is burned down, I am now obliged to build a barn. I want to build it in accordance with friend Terry's forthcoming new book; and I mean to have the stables, both for cows and horses, made so they won't freeze in any weather, and I suppose sub-earth ventilation will do it. Our poultry-men, especially those who produce eggs in winter, ought to be interested in this matter, as well as those who winter bees. You see, this is a broad subject, and one of great moment to a large class of people besides bee-keepers.

THE CONGREGATING OF DRONES.

DO DRONES FLOCK TOGETHER IN LARGE NUMBERS? AN INCIDENT THAT SEEMS TO PROVE THAT THEY DO.

SOME time in June, 1885, friend John Williams, who lives near here, called my attention to the fact that he thought drones were congregating, above a hill, about a mile east of our apiary. On the first favorable opportunity I went with him to the hill, and this is what we saw and heard.

As we approached the highest elevation, we could hear a loud humming, very much resembling bees when swarming high in the air. The most of them were too high in the air to be seen; but occasionally one would circle lower, and, by the peculiar humming which they made, we were pretty sure they were drones. If we threw a stone in the air, it would at once be surrounded; and as it fell to the ground they would dart after it and follow it to within fifteen or twenty feet of the ground. There seemed to be vast numbers of them, extending along the ridge of the hill for some distance, and they must have come for miles around.

Returning to the apiary I watched the drones as they flew from the hives, and nearly all of them flew toward the hill from which I had just returned. Now, I believe that drones congregate in large numbers, and the queen, attracted by their loud humming, flies among them and is fertilized. I do not know that there is any thing new in the above; but of one thing I am pretty sure, that there is no use trying to get queens purely mated every time, if there are drones of other races within five miles. Queen-breeders should be careful how they advertise "no black bees near here."

RETURNING SWARMS TO THE PARENT COLONY.

Our bees commenced swarming about May 25, 1885; and as the indications for a good honey season were not very good, we returned all but a few of the earliest swarms to the parent colony. By so doing, in a poor season we obtained a fair yield of honey (70 lbs. per colony), and kept them strong for winter. My experience has been, that swarms returned in this way work with the same energy as swarms hived in empty hives; and after experimenting pretty thoroughly in trying to prevent increase we have found no other plan that has proved to be so satisfactory as this. I am well aware that many would not succeed with this method, for the reason that, many times, swarms returned in this way are inclined to swarm again, therefore the novice would probably, after a few trials, give it up in disgust, and try some other plan to prevent increase. It should be remembered that, after returning such swarms, we have a powerful colony, and therefore they need an abundance of room. We usually remove two or three frames of brood from the center of the brood-nest, and supply their place with empty comb or frames of foundation. Great care should be taken, to see that every queen-cell is cut out; for if one is left, they will be pretty sure to swarm again. I know you will say, friend Root, that they can build more cells. Yes, they can, and will sometimes; but, once get them at work again, and see to it that neither the queen nor bees get out of room, and they will stay and give us such a yield of surplus as will pay for all the trouble we have had with them. O. G. RUSSELL.

Afton, Chenango Co., N. Y., Feb. 8, 1886.

Many thanks for the valuable facts you give, friend Russell. Something in regard to this matter has already appeared in our back volumes, but I believe we have never had any thing as straight and direct as the testimony you give. I have heard the drones humming in the air, just the way you mention, but I could not get a glimpse of them. What astonished me at the time was, that there seemed to be such a very great multitude of them; in fact, I could hardly conceive how there could be drones enough in several square miles to make such a roaring as I heard, and I believe you are right about it. This makes it an easy thing for queens to be fertilized quickly and surely, but it also makes it a difficult matter to get pure queens while there are bees in the woods, or in apiaries, even several miles away.—Returning swarms to the parent colony will doubtless work well where there is only a moderate yield of honey; but where swarming gets to be a mania, I think it would only complicate matters by making swarming incessant.

EGG-LAYING OF QUEENS.

SOMETHING FURTHER ON THE SUBJECT, BY FRIEND CHARLES DADANT.

IN answer to my article of Feb. 1, p. 95, Mr. Cook says that he doubts that animals drop eggs, "at just such a time, irrespective of surroundings." Well, let him put a laying hen under a box for 24 hours, and he will see her unable to prevent her egg from dropping, although she would have preferred to lay it in her nest. If a hen is unable to keep her egg, how can a queen-bee, which, according to Mr. Frank Cheshire (*Bees and Bee-keeping*), lays, in 24 hours, twice and even four times her weight in eggs?

For at least half a century, some French bee-keepers, with straw hives, have been accustomed to make artificial swarms by drumming out part of the bees. In order to ascertain the presence of the queen in the swarm, they put it, for a few minutes, on a black cloth. The white eggs, which the queen, if present, has dropped on the cloth, are easily seen, and show whether the operation has succeeded. According to the theory of Mr. Cook, as accepted by the leading bee-keepers on both continents, the queen not only knows the sex of her eggs while laying, but she knows, also, that her sons will be larger than her daughters; she knows that the colony has no need of drones before the swarming season; and she is endowed with such presence of mind that she does not make any mistake — laying drone-eggs in large cells, and worker-eggs in narrow cells. Yet, according to Mr. Cheshire, the brain of the queen is small, as is also the brain of the drone, and consequently the queen is far from being as intelligent as the workers, whose brain is comparatively large, and which, by their building of comb, their gathering and storing of provisions, their care of the brood and of the hive, etc., show that this enlarging of brain corresponds with an increase of intelligence. Yet this intelligence of the workers is not sufficient to enable them to discern a drone-larva from a worker-larva, since they make, sometimes, the blunder of trying to raise queens with drone-larvæ. Is it admissible, that, although less intelligent than the workers, the queen would know better the sex of her offspring? I think to be able to explain the whole process of this laying of the queens without resorting to imagination or the supernatural, by referring only to a natural law.

To keep every thing in its place; to perform every chemical change; to preserve the life of every being; to insure the perpetuity of every kind, nature uses a single force, or power — *attraction*. It is the same force which keeps the innumerable worlds of the universe in their relative positions to each other; which keeps the earth and the planets revolving around the sun, the moon around the earth, and prevents all the matter composing our planet from dispersing into space. It is the same force, also, which attracts the slim sprouts of a potato, forgotten in the cellar, toward the dim light of the window; the same force which attracts the rootlets of plants to the bits of manure scattered in the soil; the same which directs the anthers of some flowers to bend toward the pistil to spread on it their fecundating dust. It is the same force which, under the names of appetite, desire, love, instinct, etc., directs the animals toward the acts which keep them alive and perpetuate their kinds. All these acts are accomplished blindly by the animals. Nature does not take the trouble to tell the cow, "You will nurse your calf, to keep it alive and growing." Nature does not say to the calf, "You will suck and eat, to live and grow." She gave to the cow the blind desire of nursing her calf; and she gave to the calf the blind appetite for sucking and eating, and she remunerates both with a pleasure. For not only does nature use *attraction* to attain her aims, but she remunerates with a sense of pleasure the gratification of every desire. Such being the *universal* and *unique law* used by nature to direct the acts of all beings, let us see how it works with bees.

As soon as a queen experiences a desire to meet a drone, she goes out of the hive. She does not think, "I will have my spermatheca filled with spermatozoids, then I will use these spermatozoids, one after another, to change the sex of my eggs; for I know that, if not impregnated, they would hatch drones only, and drones are not able to do the work of the hive." Such would be her reasoning, if we were to adopt the theory of the free will of queens. To meet a drone the queen goes blindly, excited by her desire; and afterward she blindly impregnates her eggs, experiencing, also, the desire of their impregnation, and is remunerated with a pleasure. This act of fecundation being double, the desire ought to be double also. The desire for this impregnation is easily proved by the fact, that, in early spring, all the eggs which a queen lays are worker, or impregnated, deposited in narrow cells. The queen avoids the large cells given by the bee-keeper, who wants drones. As her eggs don't mature very fast, she takes time to select narrow cells. But later, when the eggs drop at the rate of one every ten or fifteen seconds, she is compelled to lay them as they come, not having time to hunt for small cells, in which she could more readily make the necessary motions to impregnate her eggs.

This desire also explains how a queen never complains of having only narrow cells at her disposal. She doesn't care for large cells, and the race of bees would be doomed for want of drones if nature had not put a check to her desire to impregnate all her eggs. This check comes from the workers, who take care to prepare large and deep cells. If we refer to the same law of attraction, we shall be able to explain, also, this building of small and large cells.

The queen is but partly mother. She can lay eggs, but she can not nurse her offspring. On the other side, the workers are partly mothers also. They do not lay, but they nurse; even more, they suckle the young.

For at least forty years it has been known that the workers have two pairs of glands in their heads and one pair in their thorax. The anterior pair of glands of the head is absent in the queens and in the drones. They are fully developed in the young, and atrophied in the old workers. It is in these glands that the milk, used by bees to nurse the young larvæ, is secreted. Mr. F. Cheshire thinks, also (and, to my mind, justly), that the same milk is used to feed the queen and incite her to lay. The operating and subsequent obliteration of these glands correspond with the double aptitude of bees as nurses first, and as store-gatherers afterward. While young, they like to take care of the queen, and to nurse the larvæ: when old, they are attached to the fields, and like to store provisions. When young, this devotion to the queen incites them to comply with her desire to have all narrow cells; and as long as she keeps pace with the building of the comb by filling the cells with eggs, no other than worker-comb is built. When old, the desire to store incites them to build store, or large cells; and if the harvest is abundant, or if the prolificness of the queen is equal to the rapidity of the building, or if the queen is missing, the influence of the old workers prevails, large cells are built, and in the height of the breeding season the queen is compelled to fill them with eggs.

Let us remark right here, that the same law applies to the human family. A young mother will gratify all the desires of her young children, regardless of cost, while a grandmother will be more careful about expenses. She will mend old clothes, and economize, to save or to acquire property. The drying of her breast, like the drying of the milk-glands of worker-bees, changes the aptitudes and the desires in both cases.

This theory has not just emerged from my mind. I explained it in some European papers about seventeen years ago, and I am confident that no other can explain as well this one of the mysteries of the bee-hive. Yet something remains unexplained. Is it the width or the depth of the drone-cells which prevents the queen from impregnating her eggs? *There* is a field open to the investigation of Mr. Ernest.
CHAS. DADANT.

Hamilton, Ill., March, 1886.

Friend D., I do not know but that we are all getting into deep water in this subject. I think I can accept most of your reasoning; but in regard to old bees not being able to feed larvæ, if I remember correctly, when this was discussed some time ago somebody proved that old bees could care for the larvæ and food, just as well as any, where they are obliged to. Perhaps somebody can point out where it was.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER IV.

THE DONATION PARTY.

A FEW families belonging to Rev. Mr. Meek's congregation lived about six miles south of his church, on what was called Crab-Apple Creek. There were not enough of them to form a church of their own; and as they lived so far from the church, and were not able to attend regularly, Mr. Meek often preached for them and their neighbors on Sabbath afternoons. Thus they had many pleasant and profitable meetings in their little red schoolhouse, and he finally succeeded in organizing and keeping up a real live Sabbath-school there. His labors for these people were much valued by them; and every winter they and a number of their neighbors made a donation visit to the parsonage. These were memorable days to the Meek children. Those honest farmers came in their large farm wagons, laden with all kinds of farm products, which filled Mr. Meek's cellar, pantry, and feed-bins, until the poor man was actually harrassed to find places in which to bestow his goods, and even meditated doing as the rich man in the parable did - pull these down and build greater. Usually these farmers were accompanied by their wives and children, who brought baskets well filled with provisions.

A table was set, reaching from one end of the dining-room to the other, on which were placed the contents of the baskets. The minister and family, although in their own home, were treated as guests, and placed at the head of the table, around which the others gathered, and due justice was done to the good things before them.

There was always abundance of talk and laughter, and all present seemed to enjoy the visit very much. On this occasion some one had brought a comb of nice honey. When it was passed around it turned the conversation on bees and honey. As Jane and Tommy now knew something about bees, they were interested and amused at what they heard.

Mrs. Cole passed the honey without taking any, saying, "I always liked the taste of honey, but I do not eat any, because I learned that, when the bees suck the honey from the flowers, they swallow it and carry it to their hives in their stomachs, and then they throw it up into their cells. I could not think of eating what had come out of a bee's stomach."

Mr. Meek replied, "Mrs. Cole, you are a little mistaken. Bees do not carry honey in their stomachs, but they are provided with a little sack for that purpose. You know the little animal we call a ground-squirrel, or chipmuck, has a little sack in each cheek, in which it carries grain and nuts to its hole; so the bee has a little sack, not in its cheek, but in its throat, in which it carries honey to its hive. You know that, in all animals, there is a pipe that extends from the mouth to the stomach. In the worker-bee this pipe is really a little sack, called the honey-sack. We might almost call it an extension of the mouth. The stomach is beyond, and no honey passes from this sack into its stomach except what is needed for its food. If we say the bee carries the honey to the hive in the back part of its mouth, it would be nearer the truth than to say in its stomach."

Mrs. Cole asked, "Is it nice to eat what comes from a bee's mouth?"

Mr. Cole said, "My wife uses sugar, molasses, and the different kinds of syrups sold in the stores, thinking these cleaner than honey. I have been south, and have visited sugar-manufactories. If I should go into details of what I have seen in manufacturing sugar and molasses, I guess she would conclude that the cleanest sweet we have is what we get from the bee-hive."

"Yes," said Mr. Meek, "not only the cleanest, but the purest and best. Molasses and syrups in these days are often made from corn, out of a substance called glucose; or, at least, glucose is frequently mixed with these. All such syrups are demanded by the people, clear and nice looking. To make them so they are treated with acids and various drugs, which tend to make them unhealthful as food; or, at least, I have been told so by physicians. How different with honey! Nature, which is only another name for God, forms the honey in the cells of the flower. The little bee, a nice cleanly insect, sucks it from the flower, and carries it in the back part of its mouth to its hive. I have read that learned men, by many experiments, have decided that the honey is not changed in the least by being thus carried. It is just the same in the hive as in the flower, only the heat of the hive boils it down, as it were, and makes it thicker. I think nice comb honey like this is the purest and cleanest sweet you can obtain. We might say it is just as it comes from the hand of God himself."

"How about the wax?" asked one in the company; "is it gathered from the buds of trees?"

"No," said Mr. Meek. "Bees do obtain a substance from buds of trees, but it is not wax. It is called propolis, and it is a kind of pitch, or bee-glue, and is used to glue up crevices in their hives. Wax comes from the bodies of the bees. It is a kind of bee-sweat, or bee-fat. On the back part of the bees' bodies are five rings, and the wax comes out at the joints of these rings in what are called wax scales. When bees secrete wax they eat much more honey than at other times."

Here Mr. Jones, an Irishman, said: "Sure an' bees must be curious lads, if they know how to do all these things. Faith, an' I believe I would keep bees if I knew where to buy some. Do you think, Mr. Meek, it would cost much to buy a couple, so I could get a start?"

Mr. Meek replied, "I suppose you mean a couple of colonies of bees."

"No," said Mr. Jones, "I mean a couple of bees. A cock-bee, and a hen-bee, or whatever you may call them."

A roar of laughter greeted this remark.

Mr. Jones looked around inquiringly, as though he could not understand why they laughed. Mr. Meek explained that his idea of starting out in the bee-business, with only two bees, was rather funny.

"Why should that tickle you?" said Mr. Jones. "You all admire my flock of White Leghorn chickens, and I began that flock with just a single pair—a cock and a hen, and now look at them. Why, this fall I had over two hundred—all birds of a feather. Why can I not begin with a couple of bees?"

"Bees are quite different from chickens," said Mr. Meek. "They will not live and prosper, unless in a hive, and that must contain a queen-bee and several thousand workers."

For some time they joked Mr. Jones about his cock-bee and hen-bee, and then Mr. Smith told a joke about one of his neighbors, an Irishman who had recently come to this country, and bought a small farm near him. One hot day, said Irishman was plowing his potatoes with a quiet, gentle old mare. In one corner of his field were some hazel-bushes into which he drove the animal, when all at once she began to prance and kick, and, turning around, rushed across the field as though some terrible thing were after her. Jerry manfully held to the lines and plow, and finally quieted the animal, but not until his shouting at her to stop had brought his wife to the field to learn what was the matter. Jerry asked his wife to hold the lines while he went to the hazel-bush to investigate the cause of the runaway. He came back with the news that there was a nest of bees in there on a little bush.

"Now, Peggy," says he, "if you will bring me the little box that is by the well I will put them into it, and they will make us honey."

Peggy returned with the box, and Jerry went cautiously into the brush; but he soon came out as rapidly as his old mare had done; and from the way he flung his arms around, it appeared as though he had a dozen arms at least. In telling Mr. Smith about it afterward, Jerry said, "I was sure I was killed; about fifty of the bees give me a dab, and each one raised a lump as large as a walnut."

Mr. Smith said, "Probably they were not bees at all."

Jerry asked what bees looked like.

Mr. Smith said, "Bees are about the size of those green-headed horse-flies you see about your team; they are brown, and some are yellow."

"Well, then," said Jerry, "those of mine were no bees at all, for they were black, had bald faces, and were as poisonous as a rattlesnake."

The company at the table laughed heartily at this, for all knew that Jerry had been trying to hive a nest of white-faced hornets.

Mr. Smith continued, "Poor Jerry had nothing to laugh at. The stings made him so sick he had to quit work, and was in bed most of the afternoon. His face swelled until both eyes were almost closed. There is one thing about bee-keeping I can not understand. Men who keep many colonies of bees will work among them day after day. I do not think a person can work with them without receiving some stings. A single sting will lay me aside from work. How can they stand it?"

Mr. Meek replied, "The pain and swelling caused by a sting do not come from the wound, but from the poison left in the wound by the sting. Our systems will become accustomed to a poison, so that it ceases to affect us. Tobacco is a poison. When a person begins its use, it sickens him. He experiences evil effects from its use; but by and by his system becomes accustomed to the poison, and these effects no longer follow its use. In like manner, after receiving stings repeatedly the bee-keeper's system is no longer affected by the poison as at the first. He does not experience the same pain from a sting, nor is it usually followed by swelling."

Mr. McMillen, a native of Scotland, next told the company about the wild bees of his native land.

He said the bumble-bees in Scotland are different from the bumble-bees in this country, in that their nests contain much more honey. In his boyhood he had spent many years herding sheep and cattle on the hills, and had found and robbed many nests of these bees. He claimed that he learned to tell a bee laden with honey, from one with an empty honey-sack, from the sound made as it flew by. When a laden bee passed him he followed it to its nest, if he could. He then marked the place so he could find it again. These nests were left until autumn, and, when well stored with honey, a number of herd-boys would go together some bright moonlight night, visit all the nests, rob them, and share the honey. He said, "I have been stung in a most terrible manner on those nights."

Mr. Meek asked, "Would you receive enough honey to pay for the stings?"

He replied "We were all poor boys, receiving only very plain food—no sweets at all, and we felt richly repaid. Each nest contained quite a nice mess of honey. Of course it was nothing like the honey we have just been eating; but I assure you it tasted much better to me then than this honey does now. After a night's robbing of nests we had honey for several days, which made quite an addition to the scanty dinners we carried to the hills. Each shepherd boy was accompanied by a dog, with which he shared his dinner. I remember my dog was very fond of this honey."

The conversation turned to other things, the meal was finished, and the children were led by Jane and Tommy to the barn, where they played many merry games until the friends departed for their homes.

To be continued May 1st.

REPORT FROM MRS. JENNIE CULP.

ALSO SOMETHING ABOUT WOMEN'S WANTS AND WOMEN'S WORK.

THE March No. of GLEANINGS is just received and contents examined. I find two things in it especially interesting to me just now. First is the statement, "Examine the bees, and, if needing stores, feed them or give sealed honey." Now, suppose you have no sealed honey (which is the case with me for the first time since I have been in the business). Would you give them sugar syrup, candy, or more maple sugar in the cake? Circumstances over which I had no control prevented my feeding as much as was necessary last fall to carry them through until fruit-bloom, and I find some of them are getting short this early. In answer, do not refer me to the A B C, for I sent that to a dear friend 50 miles distant, last year, and lent Prof. Cook's Manual to another friend in Delaware, Ohio, and Langstroth and Quinby are also on the wing; and, by the way, do not forget to send me another copy of the A B C. I do not feel as if I could "keep house" successfully without it. I have had four already; but somehow they do not stay with me.

THE PICTURE OF THE WHEELBARROW.

It just strikes my fancy. I certainly must have one, and a lawn-mower too, if a lady can use it. I will let you into the secret why I want them, Bro. Root. I have a kind of mania for having things look tidy; and having depended on "uncles and cousins" for four years, my little stock of patience is well nigh exhausted. When I ask to have my yard mowed, I am invariably met with the reply, "Oh! it does not need it yet;" and if I insist on its being done, telling them I am willing to pay well for having it done *now*, they just act as if—"well, it does not need it a bit, but I suppose I shall have to humor you." Now, that takes all the vim out of me, and, with your assistance in furnishing me tools, I will try "paddling my own canoe."

Last fall I wanted my chaff hive remodeled so as not to have to unpack in the spring. I got the idea how it could be done by using your chaff hives, when I visited you (and, by the way, I visited ten apiaries in that little trip; yours was the banner apiary. Mine the second—not in numbers, but in uniformity of hive and neatness. I have been feasting on the pleasure of that little trip ever since). I sent for a carpenter to come and do the work for me, telling what I wanted done; he sent back word he could not come. Not willing to be put off, I then went myself; he not being at home, I inquired of the "gude wife" the reason. "Oh!" said she, "he said it was just one of your whims, and he would not humor you. The hives your husband made are good enough for anybody, without any change."

I tell you that "riled" me, to think he would not even come and look at my proposed improvement, but set it down as a whim, simply because it was a *woman's* idea.

Well, the result of it was, I vowed a vow, and it was this: That if the *Lord* would give me the strength I would show some of the opposite sex that a woman can "paddle her own canoe" pretty successfully, without their assistance. Was that wicked? The strength is coming, and, one by one, I am gathering up the tools for the work. I have one hive fixed, and the remaining 55 will (Providence premitting) follow suit as soon as the weather permits.

Now, Mr. Editor, Ernest, and friends generally, for fear you will think me masculine in writing this way, I will tell you I am a little woman, not weighing over 100 lbs.; and if there is any thing I dislike, it is a masculine looking and acting woman. This I am trying to guard against.

Mrs. Francis E. Willard, President of the Women's Christian Temperance Union, says: "There is not one thing that men ought to do; there is not one thing that ought to be done, which a woman ought not to be encouraged to do, if she has the capacity to do it," and that is my sentiment exactly.

I have been slow in sending my report for 1885, not knowing in just what department to place myself. I am not discouraged, although my honey crop was an entire failure as far as surplus is concerned.

If what our president said at the bee-keepers' convention at the Ohio State Fair be true (he thought it was the fault of the bee-keepers if they failed to get a crop of honey), then you will have to put me down as a failure. But with due respect to him and his opinion, I must beg leave to differ with him. I think I am prone to be diligent in business, and left nothing undone to secure a crop of honey. The long-continued drought of the summer and fall before, and the very severe winter following, destroyed the white clover, from which we get our principal crop in this locality.

REPORT FOR 1885.

Packed in chaff hives, 47 colonies, fall of 1884, all well supplied with first-class white clover honey. Spring of 1885, all booming with bees, excepting one colony, which died. I considered that quite a success when there was such a general mortality among the bees that winter; yet no honey came of any account; at least, not enough to winter them without the aid of sugar. Wherein have I failed, if the fault is in the bee-keeper? I put into winter quarters 47 colonies, fall of 1885; two weeks ago they were all alive, and had a good fly; but for the first time since being engaged in the business, I await the outcoming with fear and trembling.

Is it true, the Ohio bee-keepers have had their convention in the city of Columbus, and I have missed attending? I certainly should have been there had I known of it. Also, what has become of Mrs. C.? Did she get her situation? Is she selling honey for some one with that mule team, wrapping oranges down south, or feeding ducks and chickens somewhere on the line between here? I have been real uneasy about her ever since I saw her advertisement, for fear that she, with her overstock of ambition, would finally land in the lunatic asylum. I am told here in the Ohio L. A. there are more farmers' wives than any other class of women; and I can account for it in no other way than in this: We are very ambitious, as a class, and we take too little time for recreation; consequently our ambition runs away with our strength, and we break down nervously. I feel condemned when I think of her, that I did not write and tell she needed *rest*, absolute *rest*, worse than she needed any thing else in this world, judging from her writings.

MRS. JENNIE CULP.

Hilliard, Ohio, Mar. 10, 1886.

Mr good friend Mrs. Culp, I glory in your ambition and energy. The wheelbarrow you speak of is exactly the thing for a woman; but I notice in your order that you mention the large size. We do not dare disobey orders, but I wondered why you chose the large one when the small one seems so particularly designed for women, especially for small women like yourself.—I agree with you, that it is your privilege to have as many whims as you please, providing you pay for them, as we know you of course do; and I want to say, for your encouragement, that it is not women only who have been treated as you have been, but I often find men who are employed here on our grounds who refuse to do what I order them to do—or, at least, won't do it without a controversy, because they think it is one of my whims, even when I am perfectly at home in the matter, and they don't know any thing about it at all. I suppose there are extremes both ways; but I think a mechanic not only stands in his own light, but is a little out of his head, when he objects to doing what he is paid for doing, because, from his standpoint, it looks like somebody's whim.—In regard to rest, I do not believe I quite agree with you, my good friend. May be farmers' wives get to the asylum because they are held by force of circumstances down to a sort of work that is to them drudgery; but I think these same women would get mental health and happiness by a change of work that might require more physical exertion than what they have been having. I, too, am small for one of my sex, and people talk to me continually about rest—yes, doctors too; but they are mistaken. I know perfectly well what kind of rest I need. A few days ago, after I had been reading letters longer than I ought to have done, I felt as if I were all coming to pieces, and as though my last days were near at hand. I took a brisk walk in the open air, but it did not seem to do a bit of good, But I found something that did cure me perfectly, and in less than half an hour too. What do you suppose it was? Why, I went and got a potato-fork that is just to my notion, in weight and make, and then I went out into the garden where the new agriculture is just beginning to "bud and blossom," and I spaded the dirt for half an hour. By that time I felt perfectly well, full of spirits, ready to fight (in any good cause), or jump over a picket fence. Do you know why? Why, I simply needed muscular exercise, coupled with some kind of work that my heart was in. The sight of my beautifully growing cabbages, lettuce, radishes, etc., and the thought of what that garden is going to be this spring and summer, gave enjoyment in the exercise, and made me well, when I was ready to take up the duties of the office until I was ready to take some more of the same kind of "*rest*."

EGG-LAYING OF QUEENS.

FRIEND HAYHURST GIVES US SOME MORE PUZZLING FACTS.

I AM glad to see this subject again brought up. Some time since I ventured to say something in favor of the Wagner theory, but our worthy editor laughed at me so that I thought it hardly safe to say any thing further; but with such a brave leader as Chas. Dadant, I believe I will venture a few suggestions.

On page 14, Prof. Cook says: "The fact that worker-eggs are often laid in cells which are hardly more than commenced; . . . . ; the fact that impregnated eggs are laid in large queen-cells." Are these facts? It is true, that, when comb-building is in progress, the queens will sometimes lay eggs along the edges in cells scarcely begun; but I have seen no evidence that these eggs are ever developed; indeed, I have learned to my cost that eggs laid in cells not over one-eighth of an inch deep will not produce *queens*. I stock my cell-building colonies with eggs laid in newly drawn-out foundation, and have repeatedly failed to get queens from the very shallow cells, and I ascribe the failure to eggs not being impregnated; so that now I do not use combs for this purpose in which the cells are less than one-fourth of an inch deep.

It is not to be denied, that the queens generally deposit the eggs in the queen-cells when the bees are preparing to swarm; but I have frequently noticed, when examining colonies in this condition, that the unoccupied queen-cells have their opening reduced to about the worker size; these are afterward enlarged to accommodate the growing larvæ. One comb will often exhibit a number of cells in the various stages of growth, from those not yet tenanted to those from which the young queens are nearly ready to hatch.

The mother-wasp, referred to by Prof. Cook, has the opportunity of enlarging or reducing the size of the opening of the cells in which she deposits her eggs. Is it not probable that a careful observation of *all* of her work will develop the fact that she does this?

Another strong point in favor of our theory is the fact mentioned by me in the article heretofore referred to; namely, that bees that have nothing but drone-combs for their brood-nest will reduce the size of the openings of the cells to that of worker-comb by building a rim around the edges. Why do they do this, if the size of the cell has no effect on the sex of the egg? I had a case of this kind come under my notice last summer. Having a good young queen from which I wished to obtain some drones, I gave her a full sheet of drone-comb in the center of her brood-nest; but the workers (the scamps!) concluding that it was not good economy to raise drones at that particular time, built rims around the edges of the cells, and raised quite a lot of workers, much to my disappointment. I have a great respect for the intelligence and reasoning powers of the queen, and I am not willing to admit that she is merely an automaton in this matter. I have no doubt that she knows just what she is about when depositing her eggs in the various kinds of cells; but it appears to me that the weight of evidence is in favor of the proposition that external mechanical means decide the sex of the eggs, instead of the accurate manipulation of internal muscles, which in higher animals are involuntary in their action. E. M. HAYHURST.

Kansas City, Mo., March 8, 1886.

Thanks, friend H., for the additional light you throw on this strange subject; and, by the way, the point you make is a good illustration of how very faulty our reasoning may be, even when we think it is very clear and plain. I have seen queens lay in the foundation, where the cells were very shallow and had just been started, and I took it for granted, as a matter of course, that she knew what she was about, and that worker-brood would be the result of this egg-laying. But when you pin me right down to it, I have to confess I do not know whether those eggs ever produced worker-bees or not. We will try to have that matter determined this summer. I have often seen drone-comb drawn out with a ring of wax, as you mention, where the bees wanted to raise worker-brood in the drone-comb. Now, I shall claim a little on my theory right here. It was the bees, of course, that put the ring of wax around the drone-cells, and, therefore, it was the bees that decided whether drones or workers should be raised. Now, why isn't it the bees all the while, and not the queen that determines the sex?

HOW TO EAT EXTRACTED HONEY.

HOW TO PUT THE CORKS IN THE MUTH JARS.

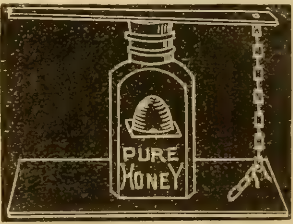
WE all know that we can not taste honey in our stomach; it is while it is in the mouth that we taste it, and Prof. Cook has truthfully said that the point of the tongue is the organ which appreciates it in the highest degree. When you spread honey on bread, I do not know of more than one way to eat it. If you like it "clear," just try it this way: Take a knife or spoon and just dip the point in the honey, then "lap" it off, using the tip of your tongue; repeat as often as you like, all the while chewing the honey, and rolling it as a sweet morsel under your tongue. Not long ago two boys bought a pound of honey at our store, and after warming it at the stove they actually *drank* it.

PUTTING CORKS INTO BOTTLES.

How do you put the corks in the Muth honey-jars? I have never seen it done, and don't know what is the best way. At first I tried putting them in with a hammer, but I soon found that jarred out a fine dust from the cork, which fell on the honey. I then made a press, which I am still using. Take a hardwood board, about 6 x 10 inches, for a base, and a lever of hard wood about 1 x 1½ x 16. Connect the lever to the base by four or six strands of heavy wire, making a loose joint near the lever. The lever and base should be just as far apart as the bottle is high. In sealing the tops, do not use pure beeswax, but take 1 lb. of beeswax and 2 lbs. of rosin; it is much better, and a great deal cheaper. Use it warm, but not hot. C. W. COSTELLOW.

Waterboro, Me., Feb. 20, 1886.

Your method of tasting honey "clear" is very similar to the way we test samples of honey sent to this office. I grant, that, to get the full benefit of the delicate flavors, we must taste the honey in the way you describe. A good many small vials are mailed here for the opinion of the editor of GLEANINGS. Running the point of his penknife down the neck of the vial, he withdraws the blade, and, with its crystal drop adhering, transfers it to the end of his tongue. If I happen to be present at the time, I sample it in like manner. It is quite essential that one or more should express their opinion upon the honey, as what would be a disagreeable twang to one might be a pleasant flavor to another. In general, however, the opinion of one or more will be found to agree; and if there is an unpleasant flavor, as of fall flowers, it is pretty sure to make itself manifest.—You ask how we insert the corks of the Muth jars. If you will turn to page 846, last year, you will see a cork-presser there illustrated and described, which we use in bottling honey. Having reduced in size the cork by means of this little implement, we then force the cork into the neck of the bottle with the palm of the hand. From your description I had the engraver make a diagram like the following, and the plan upon which it works will be readily apparent, I think. It is shown as pressing the cork into a Muth jar, the cork being just below the lever. The whole of this lever is not shown, and should be of such a length as to produce a very considerable pressure upon the cork when the hand



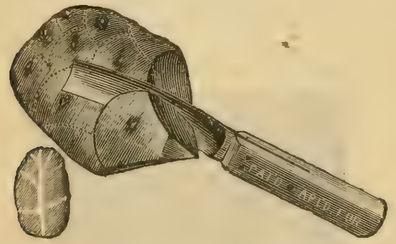
A DEVICE FOR PUTTING CORKS INTO BOTTLES.

is exerted on the extreme end. Though friend C. does not say so, it occurred to me that he probably had his chain long enough so that there would be a little surplus, or its entire length as long as the tallest jar. By means of the hook in the board, and the separate links, the chain can be hitched so as to be adapted to any desired height of bottle. The same principle can be tried by placing a jar in a suitable position upon a bench. Next nail a cleat at the proper height in the siding of the work-shop over the bench, and then with a suitable lever (one end of which is placed under the cleat) the cork can be pressed into the bottle. For different heights of bottles, cleats can be nailed at various elevations. Perhaps the latter plan would be found preferable by reason of the greater stability. ERNEST.

A KNIFE FOR CUTTING SEED POTATOES.

SOMETHING ON THE PLAN OF TERRY'S ONE-EYE SYSTEM.

VERY likely many of the friends tested Terry's system of cutting his potatoes to one eye last season. The advantages are, briefly, that we are by this means enabled to have one good strong stalk in every place, and no more. If you let ten or twelve stalks of corn grow in a hill, you certainly would not get a crop of nice ears. Where you plant a whole potato, and the whole of the eyes grow, you get a lot of small potatoes, just as you would have a lot of small ears of corn. Well, when we have got our potatoes so as to have one eye in a piece, we want as much potato around this eye as we can have; that is, we want to divide up the potato in such a manner as to have the eyes all separate, and a chunk of potato around each eye. If there are too many eyes in the potato to give each one this good chunk, select the best of them, and throw the rest away. To do this to advantage, we want medium or large potatoes. We also want the knife figured below, to cut it just right.



HUMPHREY BROTHERS' IMPROVED POTATO-KNIFE·

The saving in seed is quite an item. But our friends should remember that this plan of potato-growing requires good soil. If you take away the potato that gives the young plant nutriment, there must be rich ground or manure to take its place as soon as the young plant has used up the supply of food that starts it. We can furnish these potato-knives for an even 25 cts., packed in a neat little box, with printed instructions. If wanted by mail, add 3 cts. each extra.

CONFINING THE HEAT OF BEES IN THE HIVE.

IS IT NECESSARY TO REDUCE THE SIZE OF THE HIVE TO THE SIZE OF THE CLUSTER FOR WINTER?

OF late years, many seem to suppose that it is necessary to confine the bees on as few frames as possible during winter for their safe wintering, basing said supposition on the idea that what is needed is the confining of the heat from the bees in as small a compass as possible; reasoning from this, that the cluster of bees will be kept warm. The line of argument generally presented is, that ventilation, upper absorbents, a vacant space above and around the bees, etc., ventilates the bees to death, on the principle that warm air seeks the top of a room, and that, unless held there by a tight ceiling, the room will not become nearly so warm as it might otherwise do. Now, while there is reason in this, regarding the room, the same can not be fully applied to the bee-hive, else many colonies of bees would die which now live. Who does not remember, in back volumes of GLEANINGS, how often it has been given that the only colony surviving a hard winter in a large apiary would be one in an old box hive, which was split from bottom to top, so the snow could blow in on to the bees? or that the colony which lived was the one the owner had overlooked and left all the surplus receptacles on, the same as used in the summer? According to the views expressed by some, these colonies should have died, and those carefully packed, contracted hives should have preserved their bees alive. But the facts in bee-keeping often put fine-spun theories to flight. I have often noticed that in box-hive apiaries the best colonies of bees in the spring would be those in a tall or large hive, especially if the tall hive had stores enough in it to crowd the bees down to the bottom-board, and keep them near it all winter; yet, according to late theories, these colonies should have died or been the poorest. Here the bees were at the bottom, while, if the late theories are correct, the heat would have been at the top.

Years ago, when I was a boy, father used to put pails on his box hives in the fall, after he had taken the honey-boxes off. These pails were simply placed on the hive, and the holes leading through the top, with no covering of any kind over them; yet such colonies always wintered well. According to theory, the heat should have been in these pails, and not about the bees below; but I often found, by looking in them on moderate days, that nothing of the kind was there; but instead, the pails were full of frost, that did not melt until the weather became warm enough to melt it from the outside temperature. Again, I once cut a bee-tree, the combs of which showed that bees had lived in them for years. These combs were six feet long, but the bees had built and filled them with honey the first year, for brood had not been reared in the upper half of them, so that during the winter they had always had three feet of air-space above them, yet they did not die. Why was this, if there is truth in this small air-tight-hive principle? Well, I will try very briefly to explain my ideas regarding the matter.

A LIVING HIVE.

If we hive a natural swarm of bees in a large box, and closely watch them work, we find that they suspend themselves from the top in a compact form, appearing like an inverted cone, which, to all appearances, is nearly motionless, so that it will appear as if the bees were idle; while the fact is, that these apparently idle bees are really the hive proper, and, inside this, active work is going on, building comb, etc. This is easily seen by passing a wire suddenly through the cluster horizontally, and letting the lower half drop. Outside this living hive, or crust of bees, the temperature is often not more than 50°, while just inside they are working wax nicely with from 90 to 95°, as I found last June, by careful tests with my thermometer. It would be interesting to follow this living hive further, as it expands until it finally touches the hive; how the combs inside grow, etc., but space forbids, so I will simply note the fact that they will fill the hive unless it is very large, or the supply of honey fails too early. Now, as cool weather comes on and storage ceases, this living hive contracts, instead of expanding, thus keeping the heat inside its walls to a sufficient extent for the prosperity of the colony. As it becomes extremely cold, the walls of the living hive become more condensed, until the larger part of the bees are engaged in forming this hive; still, I have yet to see a colony which does not have an active force of bees in the center of this living hive, ready to push their way out for an attack, if the box holding the cluster is roughly disturbed. It takes some time for these crust bees to get lively enough to fly; but the inside force can do so in a second, in any colony I ever experimented with, thus showing that the material inclosing this living hive had little to do with the heat of the cluster, that being controlled by the walls of the living hive. This living hive is all the while throwing off moisture; and if the box inclosing them is of such shape that this moisture will not collect about the bees, they remain dry, healthy, and nice. This is the reason why all kinds of packing are employed to advantage, in my opinion, and why it was that A. I. Root proposed to winter bees in a felt hat not many years ago. Instances have been given where colonies of bees have been wintered successfully in a large hive containing less than one-eighth of the comb they should when filled; in fact, so little comb that the bees covered all of said comb except the outer edge all winter. But I will stop short, and close, as this article is too long already.

Borodino, N. Y. G. M. Doolittle.

Friend D., while J. A. Green and others have argued strongly that bees will winter all right when sealed up tight. even in a glass bottle, you are taking the ground that they will winter all right without any air-tight inclosure about them at all, if I understand you correctly. Well, perhaps it is a good idea to consider both extremes, and both extremes have been defended in our back volumes. I confess I have been greatly puzzled to see bees so many times winter splendidly when they were about as badly fixed, according to the rules laid down in the books, as they could be; and at other times they do not winter at all, even when they are fixed in the very best shape. I want to take exception to one point you make; that is, that there are always live bees ready to make an attack when the outer crust is rudely broken. I have several times pulled frames out of the hive, thinking the bees were dead because they seemed so motionless; and if I recollect aright, they were all tied up in hard knots, even to the very center of the cluster, and it took them some little time to wake up and get ready to sting. Where brood-rearing is going on in the middle of the winter or spring, of course they must be stirring actively. And while I think of it, I believe these colonies so knotted up in the spring had no brood, and possibly their numbers were so small their only resource to keep from freezing was to knot themselves up in this manner until the weather moderated. I have seen them thus in the fall, in the winter, and in the spring; but I believe very strong colonies usually have a warm place where bees can go on with the housework, even during zero temperature.

HEADS OF GRAIN

FROM DIFFERENT FIELDS.

HAVE THE BEES THE POWER TO CONVERT WORKER-EGGS AND SMALL LARVÆ INTO DRONE-LARVÆ?

SOME time between the 15th and 20th of October last I sold five queens. Two of them went two days before the others. In due time I looked for queen-cells, and, to my surprise, I found drones capped over, and hundreds more nearly ready to cap, these drones being mixed all through the worker-brood and in worker-comb, with a goodly number of queen-cells. Hive No. 2 was examined, and found in the same condition; No. 3 the same; Nos. 4 and 5 the same. If the size of cell has any thing to do with the fertility of the eggs, how does it happen that, after removing the queen, the bees should convert worker larvæ and eggs into drone-bees? The eggs and youngest larvæ only were drones. Now, this happened in five different hives. The combs were built on fdn. bought of A. I. Root. I fancy I hear you saying, "Drone-layer," "fertile worker," or something of that sort; but I wish to say, "Not so;" this brood was in the hives at the time of removing the queens, and young workers were hatching all around it. Her majesty reigns supreme when present, I am willing to admit, but it seems to me the bees have something to do with it in her absence. Each colony reared a fine queen; but whether they were fertilized, I can not say; but I have lots of drones, any way. I would add, these drones are smaller than those reared in natural cells. J. E. Hole.

Ripleyville, Huron Co., Ohio.

Friend H., if you will examine our back volumes you will find this matter has been discussed a great deal. While many of the friends declare positively they have absolute proof that the worker-bees can thus change the sex of eggs or small larvæ, Prof. Cook and others declare it to be an impossibility. Prof. McLain, at the convention in Detroit, last fall, remarked as follows in regard to it, as nearly as I can recollect. He said that, although he had not succeeded in proving it to his satisfaction, Prof. Wylie said, when the matter was referred to him, that he had not a doubt but that the bees might do it. This has nothing to do with the question you refer to between Prof. Cook and friend Dadant; for the above was managed by the bees after the queen was taken away.

SAWDUST PACKING, VERSUS OTHER PACKING.

Bees that were fed and packed in chaff or like protection are wintering nicely in this locality. But those that were left on summer stands, unprepared for such weather as we have been having, have perished. I went into winter quarters with 65, all on summer stands.

I have been using sawdust for packing, for four years; also chaff and dry leaves; but I should give my preference to dry sawdust. I should prefer the chaff hive stuffed with dry sawdust, also some dry sawdust next to the bees on top, to hold the heat. I have been in the habit of leaning a board over the entrances when a cold wind is blowing directly against the front of the hive, and moving it as soon as it moderates or changes its course.

Moons, O., Jan. 27, 1886. LEWIS HAINES.

HORSE POWER PREFERABLE TO STEAM FOR CUTTING UP HIVE STUFF.

I have a one-horse tread power to saw stuff for hives and boxes, and can saw two-inch plank as easily as one could wish. It is pleasant work to make hives now, and I think it better than a small engine. It costs less, and almost every bee-keeper has a horse, so the expense of running it would be comparatively nothing. It will thrash, saw wood, and pump. I think many of the friends would like them better than an engine, as there is no danger of fire. The Fearless, I think, is the best.

Amity, Orleans Co., N. Y. J. W. UTTER.

Friend D., please tell us where these horse-powers can be bought, and what they cost.

BROOD WITH THEIR HEADS AT THE BOTTOM OF THE CELLS.

I helped a neighbor take the honey from a box hive; and as I had a queenless colony I saved the queen and introduced her. Afterward I found some capped brood in the corner of the box hive. The heads were at the bottom of the cells, instead of being against the cappings. Would you remove the queen? Is she worthless or not?

CHAS. C. SCHWOB.

Moundsville, W. Va., Feb. 12, 1886.

Friend S., I have never before heard of such a thing as bees with their heads toward the bottom of the cells. If there is no mistake about it, it is something I don't understand. I would not discard any queen until I had tested her fairly.

HOW TO DISPOSE OF DRONE-EGGS, ETC.

Sometimes I find a frame of drone-comb, used in upper story for extracting, full of eggs. What is the quickest and easiest way to destroy them?

How much sulphur to a given area is sufficient to destroy moth larvæ? I am afraid of using too much, and injuring the honey. I didn't use any sulphur last year, and got along all right; but perhaps I was running a risk.

Is a room that is bee-proof also moth-proof?

Feb. 17, 1886. E. H. M.

There are several ways of destroying drone-larvæ — washing them out of the way with a fountain pump; sprinkling salt on them; standing the combs in the honey-house until the larvæ die, etc. The A B C book gives full directions for fumigating combs. Where we use Italian bees, there is not very much need of fumigating the honey; at least I would not fumigate it until traces of worms begin to be seen in the honey. A bee-proof room is probably moth-proof.

CALLING THE ROLL.

Feb. 11, roll was called. Nos. 50 and 58 failed to answer. They were chaffed in on summer stands. Of 80 colonies, half are in the cellar, right under our sitting-room, where the children romp, and where the organ is required to give forth the praises of our heavenly King. Then, too, we have potatoes in the cellar. The thermometer varies from 35° to 40°, 45°, and 48°. The bees are all O. K. yet, and seem in good shape. I carried out several colonies to day, and found no smell upon their garments—no, not even a hair singed. SAM. H. BOLTON.

Benton Ridge, Hancock Co., O., 1886.

A WARNING AGAINST USING FIRE AROUND THE APIARY.

Last Saturday I came very near losing a great number of my bees by fire. The severe cold weather we had here has killed the grass and the orange leaves. I was cleaning up, and set fire, outside the apiary, to clean up a place to make a fire outside, when the wind caught the flame and carried it right among the hives. It took all hands and the cook to put out the fire. I did not lose any bees. It scorched some hives badly, and melted some wax I did not want melted, but I thank God that I got off so well. D. M'KENZIE.

New Orleans, La , Jan , 1886.

HOW TO REMOVE POLLEN FROM OLD COMB BY MEANS OF A FORCE-PUMP.

I see by GLEANINGS of Feb. 1, 1886, page 105, E. S. Hanson makes inquiry how to remove pollen from old combs. As I have removed pollen from hundreds of old combs, I will give my process. I take wool-twine, in lengths long enough to go around my frames the shortest way. I tie two strings around each frame a little way from the ends (my frames are 15½ in. long), to hold the combs from breaking out. I take a tub or barrel, and place the combs in "criss-cross." As fast as I put in combs, I fill up with water, taking care to get as much water as possible in the cells; when the combs are all in I put on a weight to keep them under water. I let them remain 48 hours. I attach the hose to my force-pump, and put the windmill in gear, then place the comb on edge, with my finger over the end of the nozzle to make the water go in a flat stream. With a good wind, the pollen will fly out lively. Hold the nozzle within six or eight inches of the comb. I have to soak some of the combs the second or third time. In the absence of a force-pump, the extractor would do nearly as well. Not one comb in 50 need be broken if properly handled.

Valparaiso, Ind., Feb. 13, 1886. T. S. BULL.

If I understand you, friend B., your plan is to soak the pollen in water until it is soft, and then wash it out with a spray of water. I presume a fountain pump would do it nicely.

FLAT-BOTTOMED FOUNDATION AS GOOD AS ANY FOR SURPLUS.

GLEANINGS for Feb. 1 is at hand, and I think it alone worth the subscription price. I used some flat-bottomed foundation last season. The thin, for sections, did as well as any; but the thicker, for brood-frames, was nearly all worked into the natural shape; that is, the bottoms of the cells were worked down into the three little lozenge-shaped plates, the same as in natural comb. I don't know whether this is always the case or not, as the bees were not doing much at this time. The weather so far has been very favorable for bees, the thermometer having been below zero only once, and warm enough for them to take a good fly every few days. There is no sign of dysentery among them yet.

FRED W. CRANSTON.

Woodstock, Champaign Co., O., Feb. 2, 1886.

Friend C., we suppose you mean the flat-bottomed foundation is as good as any after the bees have got the shape of the cell to the natural form; but the question then arises, How much time does it take the bees, when they are busy with a crop of honey?

DRONE-TRAPS, AND SOME SUGGESTIONS REGARDING THE SAME.

I experimented last year with Alley's drone and queen trap, and in each case, when I had a trap attached to the hive, the queen was caught when the bees swarmed, and the swarm would return, and settle on the trap. I think that, by having a cone attached to the Jones' guard, I can use the same as a queen-trap, and have automatic swarming in my apiary by simply putting one end of a wire-cloth tube over the cone, and letting the other end of the same enter the box or hive, with entrances secured by perforated tin. The box or hive may be set on or near the hive which is expected to swarm. The queen and some of the bees, when they leave the parent hive, will enter through the tube into the box or hive prepared for them. The returning swarm will follow, and I shall have only to move the box in the evening to a new location, and the swarming is accomplished without any watching or any attendance of the bee-keeper during the day.

If you have tried this plan, let us have your experience.

C. H. GROTE.

Mauston, Juneau Co., Wis., Dec. 14, 1885.

Your idea is tiptop, friend G., in theory; and all that remains is for somebody to put it in practice. I believe we have already had arrangements that were somewhat similar in plan of working. None of them, however, seem to have come into general use.

DOES BLASTING ROCKS WITHIN THE VICINITY OF HIVES DISTURB THE BEES?

I live right in the city. My lot is 50 by 125, with a large house on it, so I have but little room to keep my bees. I work in the shop, 1¼ miles from home. When my bees swarm my wife telephones to the shop, and I come home and hive them. I sold three hives of bees for $18.00, and have three more engaged for spring, if I have any left. They are building a sewer right past my hives. They have to blast through solid rock from 5 to 10 feet deep. They have from 20 to 30 blasts a day, and I think it disturbs my bees, for I find a great many dead bees at the entrance.

MARSHALL DARLING.

Waterbury, Ct., Jan. 2, 1886.

Friend D., if the blasting is to continue any length of time, I think I would fasten the bees in the hives and move them away for a while.

HOW SOON SHALL BEES BE PACKED FOR WINTER? ARE CHAFF HIVES DESIRABLE?

A bee-man met me a short time ago, and in the course of our conversation he turned to bees. He asked me if I had fixed up my bees. "Yes," I said, "early." He said he did not believe in fixing them up complete so early for winter, for he thought it was just like a person putting on all his winter clothing in October. When the cold weather would come, he could not feel them on him. What say you, Mr. Root? I have put my bees away in sawdust hives, and I spoke to another bee-man about leaving them in the sawdust hives all summer, so that they might not be too warm. Well, he said he had tried bees in chaff hives, and they never gave nearly as much honey as hives that were out and exposed to the hot sun. So I thought I would refer the matter to you.

DONALD STEWART.

Nairn, Ontario, Canada, Feb. 1, 1886.

Friend S., I suppose the locality of Canada might make some difference in the matter; but reports from localities, widely different in climate and temperature, have invariably shown that bees make more surplus honey in chaff hives than in single-walled hives. Your friend can easily satisfy himself of this by trying a single-walled hive and a chaff hive side by side. During hot summer days the bees in the thin hive will crowd out in great numbers, on account of the heat, while those in chaff hives will remain comfortable inside. We greatly prefer chaff hives for summer as well as for winter. This is true, however, that there are times in the spring when the warmth of the sun is beneficial to thin hives, when chaff hives, on account of their extra thickness, are not warmed up at all. On this account, it has been several times suggested that the outer covering be made of glass, inclosing a dead-air space inside of the chaff. During winter and spring, the glass would keep off the cold winds, but permit the rays of the sun to pass through readily, warming up the bees as it warms up our solar wax-extractors; and it warms them up nicely, even when the weather is zero outside. The objections to such a hive would be, first, the expense; second, without something to shade the glass, when the sun becomes too warm it would melt the whole inside of the hive down, and more or less supervision and manipulation would be necessary. With a house-apiary it might be managed better; and if it were desirable to start bees to breeding very early in the spring, there is hardly a question but that a combination of a greenhouse and house-apiary would fix it to perfection.

THE GRANULATION OF HONEY NOT CAUSED BY BEING EXTRACTED EARLY.

I believe it is generally admitted, that all pure honey will granulate at the approach of cold weather, which I find is not correct. My honey has not granulated, neither did it last year, kept in a cool honey-house, in open tin cans (that is, loose covers); also in light barrels; yet there is no appearance of granulation. I have kept bees for quite a number of years, and have never fed, all told, five dollars' worth of sugar to bees; and if my honey is not pure the bees have "played off" on me. My honey is Spanish needle. One writer, I think, said that if pure honey did not granulate it was for the reason that it was extracted too green. In answer to that, my sister, living one-fourth of a mile from me, extracted some before any of it was capped over, and hers granulated at the apppoach of cold weather, and my honey stood in the hives a month after the honey season closed, and was perfectly ripe. All was

gathered from the same source and at the same time. Three years ago my honey was partly gathered from what we call "jack-oak;" and that year it granulated.
R. ROBINSON.

Laclede, Ill., Feb. 15, 1886.

Since you mention it, friend R., I am inclined to think that well-ripened honey is not as much inclined to granulate as when it is "green," as we often term it; and it also occurs to me that honey from Spanish needles is not apt to granulate when it is thoroughly ripened. We have had some of a beautiful amber color, so thick that a saucerful could be turned over without spilling; and for all that, even zero weather produced no signs of granulation.

ARE THEY BLESSINGS?

Though I differ with you in many things, I fully agree with what you said recently in GLEANINGS, in regard to considering honey-yields as blessings from God, and that it were perhaps safer to send us more of them, if we would regard them as such. By the way, is it quite fair to call the honey-dew we have had, "bug-juice," and the like unthankful terms, when many could have considered it a blessing, as it came in a time when bees were getting comparatively no honey? I extracted it mostly, and used it for stimulative feeding; but as I did not know what it was, and did not extract all of it, I had considerable loss, but am the wiser for it.

Marshallville, O. C. WECKESSER.

Thank you, friend W. You are right, and we will try to stop using any term that sounds even in a slight degree disrespectful to the all-wise Creator. The honey-dew has indeed been a blessing to us in our business, for it has kept brood-rearing going when it would not otherwise have done so without feeding; and with the large force of honey-gatherers in our apiary, it is generally all worked up into brood, so it does no harm. Many of these things that seem at first to be hindrances can be turned into blessings if we handle them rightly; and through it all, our attitude of heart should be, "Thine be the praise and the glory."

ROACHES IN BEE-HIVES.

I have a few questions to ask about bee-keeping. Did you ever have roaches in your bee-hives? I have two hives infested with them. I have changed the bees into new boxes, and they are still in them. I see they pick out the young brood in the combs. Have you any way of getting rid of them?

Post Oak, Mo. J. S. BRUCKART.

Friend B., the trouble with roaches, I believe, belongs to the Southern and Middle States. We have none of them here. From the reports given, I have been inclined to think they did but little if any harm. If they are picking the brood out of the combs, however, it is a serious matter. Will not a strong colony repel them?

LEAVING BEE-HIVES IN A SNOWDRIFT.

You advise us to leave our hives nearly or entirely covered with snow in winter instead of keeping the entrances open. Now, have you ever successfully tried that plan for one or two months at a time? I lived the first twenty-five years of my life within twenty-five miles of Medina, O., and can fully realize the difference in the snowfall between there and here. I have often resolved to let them alone, with one or two feet of snow over the entrances; but my faith in that plan has never held out over one week at a time. This is a question of vital importance in this locality. We use chaff cushions in upper story, with an inch hole in each end of the cover for ventilation. This is an excellent locality for bee-keeping, though last season was an exception.
J. H. MANNING.

Sun, Newaygo Co., Mich.

Friend M., we have, ever since we kept bees, rejoiced to see the snow all over the hives so that they were entirely out of sight; but I do not know that we have ever had them covered up *entirely* for as long a period as two months—perhaps not more than half that time; but I have never had reason to think that a colony was injured by being covered with snow, but quite the contrary. Neither have we ever had any reports to the effect that snow would hurt bees, unless it was where the drainage was so poor that, when the sun came to thaw the snow suddenly, the wet snow, or slush, would cover the entrances. In that case, if the top of the hive were tight it might damage them.

SPEED OF BUZZ-SAWS, ETC.

When and how can I best move ten swarms in chaff hives ten rods?

3—ADAM LEISTER, 7—10, 0—70.
Brunswick, ♁ Ohio. 3 { 1— 3, 3 — 7, 7 — 10.
Feb. 19, 1886. X—$23, $20—$5, MX—$20.

Explanation: The 3 here stands for 3 years of bee-keeping. The upper row shows increase in successive years. In lower row, first figure in each set shows cash income; second figure shows cash expense for that year; X stands for "experience;" M, for "more." After name, 0 stands for surplus honey in 1885; 70, for pounds of sugar fed; work, not taken into account. At what speed do you run buzz saws and cutter-heads? A. L.

Friend L., if you can move the hives after a spell of cold weather that has prevented the bees from flying, say from ten days to two weeks, I think you will not have very much trouble. See A B C book, p. 172. There is much difference in the behavior of one colony under such circumstances, compared with that of another. Some bees will take their points and come straight back to their hive, if you should move it every few days; others will remember the location, even if they have not had a fly for a month, or perhaps all winter, and go back to the old familiar spot.—Your interpretation of your characters and figures makes one think you have been recently reading about Nebuchadnezzar and Daniel. Never mind. It illustrates how long a story can be told in a small space, and that is a lesson that a great many of us need to learn just now.—In regard to the speed of buzz-saws, it is laid down in the A B C book that the points of the teeth should move at the rate of about 8000 feet per minute; but the kind of work to be done has something to do with it; also the kind of wood to be cut. But the rule given above will be found to be not far out of the way for the generality of work.

FERTILIZING QUEENS BY MECHANICAL MEANS; FORMING NUCLEI.

I notice in GLEANINGS for Dec. 15, 1885, page 882, editorial, that Prof McLain has succeeded in "fertilizing queens by mechanical means." I have been looking for that for some time in GLEANINGS. I still don't know how, but hope that, as soon as you know, you will give it to your readers. It will be a grand thing for me and others of your readers who are surrounded by black bees and log gums. The season here has been unfavorable for bees this year, although they have made enough to winter on. I am a farmer, and do not have much time to devote to my bees. I love my bees a great deal better than I do my plow; and if I were certain that I could make money at the business, I would quit farming and go at it right. I like G. M. Doolittle's plan of forming nuclei. I have tried it a number of times, and succeeded every time. That alone has been worth to me more than GLEANINGS cost. I have introduced queens by it when other methods have failed. F. P. HISH.

Henton, Shelby Co., Ill., Dec. 21, 1885.

Friend H., I hardly think fertilization of queens by mechanical means is going to come into use very much, even if it succeeds. You will have to watch the ages of your queens, so as to take them at just the right time, and then it will be necessary for you to catch drones. The whole operation, it seems to me, is going to be too much expense to come into general use.—If I were you I would stick to the plow until your bee-business is so well established that it is a safe thing to give it your whole time; that is, make it a gradual work of letting go of farming and taking up bee culture. While the bees may give much the larger profit on the investment and labor, there are a good many risks about the business.

NATURAL SWARMING AND NON-SWARMING.

No queen, no bees; no bees, no honey. More queens, more bees; more bees, more honey. Such thoughts were in my mind in the spring of 1884; and for experiment, two strong colonies were chosen, being swarms from the same colony in 1883. One of these was to be tested by natural swarming, and the other by artificial swarming. June 4th, No. 1 swarmed, and, soon after, the old colony was divided into nuclei of one and two frames each, all having good queen-cells. One of these swarmed (a mere handful), and was hived on a comb and a frame with a little brood on it. These all raised good queens; and as soon as hatching brood could be spared from the new swarm, a frame was given to each nuclei, building them all up evenly. August 2d the new colony swarmed again, and, by division, two more colonies were made. August 13th one of the colonies swarmed and was not seen. No. 2 swarmed June 8th, and again the 24th.

The result of the season was, No. 1 an increase of ten colonies and 325 lbs. of honey; and No. 2, an increase of two colonies and 191 lbs. of honey, while the best yield from a strong colony that did not swarm was 156 lbs. of honey. There was no honey taken from the brood-chamber, which was well filled for winter supplies. The average yield of the apiary was 80 lbs. of honey. In the spring of 1885, on a farm seven miles from home, were three colonies of bees which I wished to Italianize; and as there was no one to watch them they were divided so as to prevent swarming, but failed in one instance. Three dollar queens were used, and divisions were made till there were 17 new colonies with Italian queens. The hives were well filled, and a surplus taken of 353 lbs. of honey from the upper stories. The division was carried too far for the largest yield of honey. An increase of 7 colonies in the first, and 13 the last trial, would have given a larger surplus. In the first experiment, those that I tried in 1884, allowing that the new colonies had 40 lbs. of honey each, the comparison shows that division gave 725, natural swarming 271, and non-swarming, 156 lbs. of honey. Successful as these experiments have proven, I would not advise any mathematical Californian to waste paper in calculation of what he might do with 100 colonies increased in a like ratio for five years. L. M. BROWN.

Sergeant's Bluff, Iowa, Mar. 8, 1886.

Friend B., the point you make is a good one; yet much of the success you have met, I think, depends upon the fact that your locality is not overstocked at all. On the contrary, perhaps there is honey for several times as many bees as you keep. In such cases, more honey will be secured by judicious dividing or artificial swarming, and by getting as many queens to lay eggs as early in the season as you can. When, however, you have from 50 to 100 colonies in one locality, so that the flowers are all visited, and the bees begin to crowd each other, then there will be an advantage in the prevention of swarming. I should say, that in any locality, not overstocked, more honey will probably be secured from a single colony by judicious increase than with no increase.

A TRIP TO CALIFORNIA; ALSO SOMETHING ABOUT A VISIT TO FRIEND HAYHURST.

I have recently returned from my winter's trip to California, and have been and am taking pleasure in reviewing old acquaintances and shaking hands with old friends, so I would not forget you. I find, that in central California, in the great river valley, what honey they get is of no great value, being dark and strong. There are a great many bees in the trees, sometimes several swarms in the same tree. In the foot-hills the honey, if they get any, is likely to be better, that from the alfalfa being fine. As nearly as I found out, the great honey section is in the southern part of the State.

On my way home I stopped to see friend Hayhurst, of Kansas City, and was very glad I did so. He has some of the finest bees I have yet seen, and he knows how to care for them. To prevent the queens from fighting, he cages each cell separately before putting into the nursery. It is, as Mr. H. says, a mistake to suppose queens just hatched will not destroy cells remaining, or each other, for they will so do if strong and vigorous. This has also been my experience. Who has a different report?

I arrived at home and found my bees in good condition for this time of year, and I hope so to keep them. CHAS. R. BINGHAM.

Edinburg, Ohio, Mar. 22, 1886.

WINTERING BEES UPSTAIRS IN A WARM ROOM.

Some time last season one R. F. Perry, of Clarkston, Mich., wrote me about purchasing some bees or queens of me, and incidentally dropped the remark that he never lost bees from wintering. In replying to his communication I asked him how he wintered. He replied that he wintered upstairs, with a stovepipe passing through the room. I was then very busy shipping bees and queens, and hadn't time to correspond further. His letter was laid by and almost forgotten until I saw friend Hutchinson's article in Jan. No., page 6, where the idea is advanced that the temperature of cellars may be kept even as high as 90°. Then I thought, "Why not put the bees upstairs where it is warm and dry?"

I again opened correspondence with friend Perry, and learned that for four winters he has kept bees in an upper room, through which a pipe passed from a stove below, where the family lived.

He prepares them thus: When cold weather is well settled in, the bees are quietly carried into the chamber; the covers are removed from the hives, and a folded blanket laid over the bees; the entrances left all open, the room kept absolutely dark, and as cold as possible, for six or eight days, until the bees get used to the jar of the house; then a fire is built below, and the room kept warm all the rest of the winter. Has anybody else ever tried this plan? Is it not much better than cold, damp cellars? S. C. PERRY.

Portland, Mich., March 11, 1886.

SUCCESSFUL WINTERING IN BOX HIVES; A FACT AGAINST UPWARD VENTILATION.

My father kept bees in Washington Co., N. Y., when I was but ten years old. They were kept in box hives. The hives were set up about one foot from the ground. The entrance was at the bottom of the hive, about one-half inch wide by four long. They stood on summer stands all winter, with no ventilation except at the entrance, and the top was sealed as tight as the bees could make it. I don't remember of ever losing a swarm in winter. Father moved to Lorain Co., Ohio, when I was 15 years old. I found a swarm on an apple-tree the second year. I put them in a box hive, and carried them home. They swarmed once that season, and both swarms wintered well. The next summer I cut two holes in the top of one of the hives, and put on two boxes of a capacity of about 5 lbs. each. These I took off in the fall, well filled. I laid a board over the top of the hive. In the spring the bees were dead, although they left a good supply of honey. The hole through the top of the hive was left open during the winter. A. ALLEN.

Tecumseh, Neb.

"CHAMPIONING" MR. HEDDON.

Its author may not have intended it, but the article on page 171 gives the impression that, in my review of Mr. Heddon's "separator record," I either read carelessly, or, if I found any thing upon the *opposite* side, I *suppressed* it. I did neither. My only fault, if fault it can be called, was in *not going back far enough*, although I went back twice as far as the editor said it was necessary. I went back *four* (not "*numerous*") years, while the quotations given, showing that Mr. Heddon was *once* opposed to separators, are from writings *five* years old. I have never "championed" any man, in the sense in which I have been accused of "championing" Mr. Heddon, and *never shall*. I have always fearlessly championed what I believed to be the *truth*, and shall continue to do so, even if in so doing I am frequently compelled to agree with Mr. Heddon, "or any other man." W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich., Mar., 1886.

QUIESCENCE IN WINTERING.

It has always been my aim to get the bees, while in their winter quarters, in that quiescent condition mentioned by friend Doolittle, page 212. When I can get them into that state, I always have good success, and the amount of honey consumed is remarkably small. With the experience of the past winter I have concluded that I can the most effectually accomplish it in the cellar, where, henceforth, I think the major part of my colonies will be wintered. CHRISTIAN WECKESSER.

Marshallville, Wayne Co., Ohio, Feb., 1886.

CEDAR HEDGE A GOOD WINDBREAK; HOW TO SET OUT.

A cedar hedge makes a good windbreak for bees in winter, and also a nice hedge around the houseyard or garden. It is raised as follows: Dig the trees and put them in a tub containing some water and dirt, so that the roots don't get dry, or else they will not grow; then plant them in a straight row two feet apart. Cultivate them the first two years; trim the new growth back occasionally. When they have the desired height, trim off the top. In four or five years you will have a nice green wall, so thick and tight that a bird could not get through. JOHN F. HOCKEMAYER.

Campbellton, Mo., Mar. 12, 1886.

A SUITABLE BEE-DRESS FOR A WOMAN.

I think the neatest and most convenient bee-dress for a lady consists of a linen ulster, which can be slipped on over any kind of a dress. For the head, I prefer a light straw hat, with a rim of medium width, to the edge of which is securely attached a veil of brussels net, extending clear around, in such a manner as to admit of its being drawn down over the face. This, with a handkerchief tied about the neck, completes my bee-dress. As for gloves, I leave them for those who can work in them. SARAH E. DUNCAN.

Lineville, Iowa.

REPORTS ENCOURAGING.

FROM 35 TO 50, AND 5000 LBS. OF HONEY; A GOOD REPORT FOR SWEET CLOVER.

WE commenced the season with 35 colonies, and increased to 50. We extracted 5000 lbs. of choice honey, and have been and are now selling at 20 cts. per lb. at retail. We are not selling much at wholesale. Wholesale prices are about 10 to 12½ per cent less. The honey was from alfalfa mostly; nearly all Colorado flowers furnish some honey, but nothing seems to yield every year like sweet clover. Alfalfa failed in 1884, but yielded largely in 1883 and in 1885. I use chaff hives; winter on summer stands, and last year was more profitable than any other business I struck. If 100 colonies would average as well as 50 or less, I guess I would take the 100. R. H. RHODES.

Arvada, Jefferson Co., Col., Feb. 10, 1886.

A FEW FACTS OF EXPERIENCE, FROM A LADY.

Friend Root:—We hereby hand in our fourth annual report for 1885. We commenced the season with 27 colonies; and although we worked most of the season against increase, we closed the season with 44 colonies and 827 lbs. extracted honey and 217 lbs. comb honey, and our bees all in good shape for winter. We wintered 28 colonies in the cellar and 6 in chaff hives on their summer stands. All came through in good condition. We weighed and placed them in the cellar Dec. 10, 1885. We took them out March 13th, and, weighing them again, found they had lost, on an average, 5 lbs. and 6 oz. per colony.

The season of 1885 was a peculiar one—cold and wet in the spring, and cold and wet during the honey-flow in September, which cut our crop short. Although not as good as some seasons, yet it was better than others, and we are well satisfied with the season's work. We have to work against a great many disadvantages in this locality, having no white clover or basswood; but for all that we have made money every season that we have kept bees. Nearly all who have tried the business here have failed, and given it up as unprofitable. "Doesn't pay," is the cry. Our success, though moderate, has not been through superior knowledge of bee-keeping, but to giving a strict attention to details, and doing a thing when it should be done, mixed with a good deal of enthusiasm and hard work. Had the others who have failed worked as hard as we, they probably would not have failed. Many times we have felt like giving up, as have all bee-keepers sometimes. I don't mean all, but some of them have been, and others yet will be, the worst-disgusted mortals that ever lived, and will almost wish they had never seen a bee. The dark clouds pass away, and we feel renewed strength because we have conquered, and rejoice thereat. During the past season we have formed a few opinions as follows:

That the Heddon method to prevent after-swarms has never failed with us, and is the best; that wide frames to procure surplus are as good as any. Last season our opinion was in favor of the Heddon case; our opinion is reversed this season; that there is little or no difference in the amount of honey gathered, whether bees are working on the L., Gallup, or our own size of frame, size 10×12¼, every thing being equal; that the Cyprian bees gather more honey than the Italians, but they are poor comb-builders; that hybrid Italian queens, crossed with German drones, produce better honey-gatherers than pure Italians, but perhaps no better than a pure Italian queen mated with a pure Italian drone of another strain; that we don't like clipped queens, but might change our opinion if our apiary ran up into the hundreds; that we shall have a good chance to test the merits of our five acres of alsike clover sown last season as a honey-plant, as nothing else yields honey at the time it blooms.

Rossville, Kan., Feb., 1886. **Mrs. M. F. Tatman.**

BEES DOING WELL—ONLY ONE COLONY LOST OUT OF 105.

My bees are doing well. I lost only one out of 105. I think we shall have swarms by April 1. My bees are all very strong, and have a large amount of brood. I think it will be advisable for me to extract from my upper stories, as they have whole frames of sealed honey. They are now bringing a great deal of pollen and some honey.

I think from the present indications that we are going to have the greatest honey-flow since 1882. I am getting a good many of my neighbors to quit the old log gums, and adopt in their stead the movable-frame hive. The bee-fever seems to be advancing to a very high point in this portion of the State. I think from this, if for no other cause, I can get them to improve their bees. **M. Simpson.**

Gatesville, Tex., March 16, 1886.

WINTERING NICELY.

I have 48 good strong healthy colonies of Italian bees in two-story chaff hives, all wintering well so far on the summer stands. They have plenty of stores to winter on. I fed each colony one dollar's worth of sugar last fall. I lost but one swarm, and the queen was a drone-layer, which was the result of losing it. We have had nice warm sunny days, so the bees would get a flight every now and then. From all appearances we may have a good summer for honey here this summer.

Lower Salem, O., Mar. 5, 1886. **Charles Haas.**

KEEPING A RECORD WITH THE BEES.

I went into winter quarters in 1884 with 29, and came out with one strong and 13 weak colonies. The strong one was the one to which I introduced the Italian queen I bought of you. She had more bees than three of the others put together, and I got 105 lbs. of comb honey from this one—as much as from all of the rest. In 1885 I increased to 38. I doubled up to 35, and sold one. I then went into winter quarters in 1885 with 34 in good condition. I have lost three from freezing. My bees had a good fly the 7th and 8th of February. I winter on summer stands. It was exceedingly cold here this winter. The mercury was 20 below zero.

Total receipts on bees - - - - - -	$53.00
Expense - - - - - - - - - - -	25.15
Net profits - - - - - - -	$27.85

I keep a record of all expenses and receipts, the same as dealing with my neighbors.

Cowden, Ill., Feb. 18, 1886. **A. W. Spracklen.**

LOST 4 OUT OF 15 COLONIES.

Bees are in good condition at this time; they are having a good fly to-day. I have lost 4 out of 15, fall count. I began the spring of 1885 with 5 weak colonies in old box hives; increased to 15 and took 140 lbs. of comb honey, principally from red clover. I hope to do better this season. **J. N. Davis.**

Moreland, Ind., Mar. 18, 1886.

2000 LBS. OF HONEY FROM 16 SWARMS TAKEN WITH A HOME-MADE EXTRACTOR.

We have had three or four frosts this winter, which reminds me that I have made no report yet for last season. I commenced last spring with 26 hives of bees, nearly all in old boxes, which I transferred to Simplicity hives. I made my own extractor and extracted 2000 lbs. of honey from 16 hives, and from the other 10 I got about 250 lbs. comb honey. I sold four stands, and have twenty-four to commence with this year. I received the saws you sent by mail, and was glad to know that you are so prompt in business as to correct the mistake at your own expense. I have never dealt with any one whom I would rather deal with than you, for I believe you to be honest.

Walter B. Fisher.

Uvalde, Texas, Jan. 3, 1886.

FROM 4 TO 9, AND 400 LBS. OF HONEY.

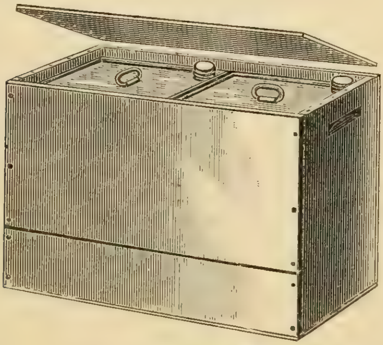
I started in the spring of 1885 with 4 colonies—3 strong, one weak; increased to 9, and took 400 lbs. of comb honey, nearly all from basswood.

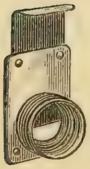
Georgetown, Iowa, March 9, 1886. **Ira Williams.**

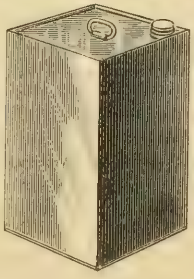
HOW SHALL WE PUT UP OUR EXTRACTED HONEY?

IRON-JACKET CANS DISCARDED.

THE package used for liquid honey by the friends in California is, at least for the most part, a square tin can, either soldered up tight or having a screw cap at the corner to pour out the contents, as shown below.







OUR NEW 58-LB. HONEY-CAN.

A square tin of itself would hardly be safe to ship by freight; but a stout box can be made to contain a single can, at an expense not to exceed 7 or 8 cts.; and where two cans are crated together, which is the usual way the friends in California do it, the outside protecting box can be furnished for an even 10 cts. The figures above explain the matter so fully, no further description will be necessary. The materials required for the can are two sheets of charcoal tin, 14 x 20, and two sheets 10 x 10. By reference to our price list you will find that the tin costs 12 cts. for the body, and about 8 cts. for the top and bottom; so the materials cost only about 20 cts. To make the can, you take the two larger sheets and lock them together so as to stand end to end. This gives you a sheet of tin about 14 x 40 inches. Square it up true and accurate, and lock the extreme ends together, making it a sort of oval-shaped can, without top or bottom. Bend it at right angles where the seams are, and then between the seams, and your can-body is done, except the top and bottom. Notch out the corners of your 10 x 10 pieces; fold the edges with a suitable folder, and they will slip on the can tight enough to solder. Put on a screw cap, as shown in the cut, and a handle made of stout wire, and your can is complete.

FRIEND T. P. ANDREWS' UNIVERSAL HONEY-GATE.

The above is shown in an enlarged view at the left, below the large cut. It is made of a piece of stout charcoal tin, 2½ x 3 inches. A piece of heavy leather is fastened by four rivets to this piece of tin. The leather is 2 x 3 inches, so that we have ¼ inch of the tin projecting on two sides. Fold this tin which projects, in such a way as to take in the tin slide, as shown in the cut. Before putting the leather on, we solder securely to this piece of tin the loose top of one of the above-mentioned screw caps belonging to the honey-cans. After it is soldered fast, with a suitable punch we cut a hole through both cap and tin. This gives us a honey-gate that will fit on any of our square honey-cans, so your grocer need have but one honey-gate, and he can attach it to his square cans as fast as he retails from them. Friend Andrews, the inventor of this honey-gate, writes as follows in regard to the whole apparatus:

SOME OF THE ADVANTAGES OF THIS PACKAGE OVER BARRELS AND KEGS.

This package has been used by myself and other bee-keepers here for the past two years, with great satisfaction. The case of 2 five-gallon cans cost 65 cts. each, with *cork* nozzle; 5 cts. more for *screw caps* like the one I sent you. They are made by E. T. Mason & Co., 247 Lake St., Chicago.

It costs less per gallon than the cheapest kegs; and no more, I think, than barrels when waxed.

The honey in these cans is sealed up *air tight*. It gets no bad taste from the packages. The cans are ready for use (can get them in three or four days). They do not *leak*. It makes a convenient package for the retail trade, with my honey-gate attached. If the honey becomes thick or granulated, it can be readily liquefied by setting the can on the stove, or in hot water. A case similar to this is largely used by the California bee-keepers.

Now in regard to the gate. You will see that it can be screwed on to the can in place of the cork-lined screw cap, which is to remain on the can till it is desirable to draw the honey. If, when the gate is screwed on tight, it is not right side up to draw from, it may be unscrewed a little, and a bit of string, or a small rubber band, put around the nozzle, and the gate screwed up again until it is right side up when tight. To make the honey run freely, a small hole must be pricked in the top of the can, in the corner furthest from the gate. If the gate should leak any, the can may be set on end when the gate is not in use. I have made a dozen or more of these gates, for the use of my customers. In making them I bought the caps—worth $2.00 per 100. I cut the tops of the caps out with a center-bit, the lip having been filed off. The corresponding hole in the tin was also cut with the same bit. I do not intend to manufacture them for sale. With heavy tin, and leather of even thickness, I think they can be made tight enough so as not to leak under as low a pressure as they would be subjected to on a five-gallon can; and if the gate should leak a little it would not be a very serious objection, as the can may be easily set on end.

To make the slide work easier, I would suggest that it be made at least ⅛ of an inch narrower than the ways in which it slides. T. P. ANDREWS.

Farina, Fayette Co., Ill., March 1, 1886.

In regard to prices of the above, we can furnish a pair of the cans in a box, screw caps and all, for 90 cts. each; in lots of ten, 80 cts. each; and in lots of 100, 70 cts. each, the same as they are offered in Chicago. The little honey-gates will, for the present, be 15 cts. each; $1.25 for 10, or $10.00 per 100. One honey-gate will answer for 100 cans or more, as you will observe. The air-hole is easily stopped by means of a drop of solder when the can is to be used again for shipping. These cans hold exactly 58 lbs., or 5 gallons, like the old iron jackets. The price of a can crated singly is 50 cts. They will, as a general rule, be shipped in pairs. A stick, one inch square, is laid over the tops of the cans, before the cover is nailed.

GLEANINGS IN BEE CULTURE.
Published Semi-Monthly.

A. I. ROOT,
EDITOR AND PUBLISHER.
MEDINA, O.

TERMS: $1.00 PER YEAR, POSTPAID.

For Clubbing Rates, See First Page of Reading Matter.

MEDINA, APRIL 1, 1886.

Though a host should encamp against me, my heart shall not fear.—PSALM 27: 3.

WE have to-day (April 1), 5240 subscribers.

ALSIKE CLOVER.

ON immediate orders we can furnish alsike clover at $8.00 per bushel. If less than a bushel is wanted, the price will be $4.25 per half-bushel; $2.25 per peck, or 18 cts. per lb.

BLUEBERRY-PLANTS.

SINCE the letters were published in regard to these, on another page, more of a similar import have come in. If Mr. Delos Staples wants to refund the money he has received for these dried twigs, he may regain his good standing, but nothing else will answer.

WINTERING BEES IN A WARM ROOM.

THE plan of wintering, on page 271, I think is a mistake. In the first place, it is a very difficult matter indeed to make an upper room absolutely dark; and after you have got it absolutely dark, my experience has been that the bees will go out when the temperature gets up to 60 or 70°. Although there may be occasions when very strong colonies would stay in their hives, as a rule I am sure it would not work.

MAPLE SUGAR AND SYRUP.

WE have now a very fine lot of new maple sugar, at 7, 8, 9, and 10 cts. per lb., according to quality. By the barrel of 520 lbs., one cent less. For the convenience of those who want a smaller package than a gallon, of the new evaporated maple molasses, we have the whole crop made by neighbor H., put up in half-gallon cans at 60 cts. per can. Neighbor H. has already, this 29th day of March, 500 maple-trees on his own grounds, dropping the crystal sap into new tin pails, and one of the most modern evaporators is to-day boiling it down into this maple syrup. The half-gallon cans are filled with the hot syrup in the sugar-bush, and a screw cap is so arranged as to seal them hermetically while hot, so they may reach our customers in as nice shape as the best canned fruit. Ten cans, 55 cts. each; 100, 50 cts. each.

KIND WORDS OF SYMPATHY SINCE THE LOSS OF OUR WAREHOUSE.

I TAKE this opportunity to thank the friends who have written such very kind letters in regard to our loss by fire, and to express my regret that it is impossible for me to answer them individually, in the kind way their letters seem to demand. If it is indeed true, that the fire was the work of an enemy, God's promise seems to begin to be verified already. "Surely the wrath of man shall praise thee."

AN OMISSION.

THE advertisements of W. H. Osborne, Chardon, O., and C. Weckesser, Marshallville, O., should have appeared in our last issue, as they do in this. In writing about this, friend Osborne makes the following strong point:

> "Perhaps it has done no damage to me, but people seem to have more confidence in regular advertisements."

Those who complain about not receiving a reply from an advertisement inserted but once, would do well to remember this.

PERFORATED ZINC OF OUR OWN MANUFACTURE.

AFTER some months of diligent toil we have builded a huge press, to be run by the engine, capable of perforating sheets of zinc about as fast as a good cow will chew up cabbage-leaves. The perforations are exactly like those made in England, which seem to give the best satisfaction, as a general thing. Our machine, however, perforates sheets only 28 inches wide by 8 feet long, making 18⅔ square feet in a sheet. Prices will be 10 cts. per square foot, or $1.50 for a whole sheet, as above. Two sheets, 5 per cent off; 10 or more sheets, 10 per cent off. Samples mailed free on application. The above low prices are because we do not have to pay duties to Canada, nor England either.

OUR NEIGHBORS OF THE BEE-KEEPERS' MAGAZINE.

A NEW price list from the above firm (Aspinwall & Treadwell, Barrytown on the Hudson) is at hand, and it certainly is a novelty in some respects. The picture of the factory, store, and shipping-house on the banks of the Hudson is quite home-like, and a description of their factory at the close of their 30-page catalogue has so much of the right ring in it that I want to make a brief extract. After describing the different buildings, we read:

> The executive department is seen on the right. There, surrounded on all sides by enough paper to make a junk-dealer happy, may be found your humble servants, pegging away at their correspondence, always happy to be honored by either a letter or order, however small, from you.

May much prosperity and many years of usefulness reward the new firm.

WRITING LENGTHY ARTICLES.

FRIENDS, something must be done to enable us to condense our ideas. It is not fair nor right to let one man occupy a great portion of the space in any issue, to the exclusion of half a dozen others. Let me suggest a little. Write more about your actual experience, and less about your opinions. For instance, we get long articles about reversible frames, from somebody who has never used them, and who opens up by saying he wouldn't have them in his apiary. Do we want such articles? Just at present, I do not believe that we do. The same will apply, a good deal of it, to the Heddon hive. What we want now is facts from those who have been working with them. Let friend Heddon send some hives to the friends in the South, where their bees are working, and in two weeks' time they can give us facts from experience. Please consider that we are a great body, and we want to hear from a great many. Cut your articles off at both ends, and give us the meat.

LOW PRICE OF HONEY.

SHALL WE RETAIL IT AT HOME, OR SEND IT TO THE CITY?

FRIEND ROOT:—In your comments upon my article in GLEANINGS, page 132, you say that you have heard of no one selling his honey for 5 cts. per lb. If you turn to the market reports you will find the quotations from 6 to 8 cts. in Boston. Some quotations say no demand for extracted honey; comb honey all the way from 10 to 15; mostly centers on 12½. My crop of honey was 8000 lbs. I have been working off 3000 in the home market; 5000 I shipped to different parties in New York. One lot was sold for 6 cts. per lb. After paying freightage, commission, and taking out cost of barrels, I find the honey nets me 5 cts. per lb. I wrote to friend Muth, our reliable cash buyer, early in the winter, for his prices for extracted basswood honey. He would give 6 cts. but I must deliver it. By the time it was put down in Cincinnati the freightage and cost of barrels would leave me but about 5 cts. per lb.

In relation to working up the home market, I have the same experience as Mr. Todd, of Philadelphia, only in a less degree. He says, "I have tried to develop a honey business here; and with a million people I can only say it is a heart-breaking job." Perhaps it is because it is Philadelphia. I have wondered many times why we never had quotations, or any indications of a honey market at all, in so large a city as Philadelphia.

Every bee-keeper who has had any degree of success has more or less competition. Other bee-keepers in his own and adjoining towns enter the markets with him; and where his crop is in tons he can not work it all off. It has been recommended as an excellent plan, to place honey on sale in stores, far and near, and visit the stores often enough to keep up the supply. The honey will have to be put up in small packages, and sold at a low price, with a commission to the grocer, which, added to the expense of keeping a team on the road, will reduce your profits again to 5 cts., or so near it that you will wish you had got rid of all the fuss and worry by shipping your honey in bulk to some reliable commission house. To show you how rapidly honey will sell when left in the show windows of a grocery, I give you the following: Oct. 11th I left 16 pails of honey with a reliable grocer in a thriving manufacturing village of about 10,000 population. The honey was put up in pails, nicely labeled. I left—

Four 5-lb. pails at 60 cts. each, to be sold for 75.
Four 2½-lb. " " 32 " " " " " " 40.
Four 1½-lb. " " 17 " " " " " " 25.
Four 1-lb. " " 12 " " " " " " 18.

My price per pail would average me 10 cts. per lb.; then adding the price of the pail gave me my prices. The last column gives the prices sold at, and the difference between that and the next column gives the grocer's profits. In six weeks after leaving this small lot I called and found a few of the smaller pails sold. A few days ago I called again and found all sold but two 5-lb. pails. The grocer thought he would want more of the small pails, but he would let me know by postal. The postal has not arrived.

At the same time I left some comb honey, and that was as slow sale as extracted. In another village I have a cash purchaser for small lots put up in the Jones pails. His sales have been a little better, but not enough to give much enthusiasm.

There is one peculiarity about the sale of honey that I presume every bee-keeper has noticed. You may have an excellent customer for your honey for a time, when all of a sudden he stops short off; and when you inquire the reason he tells you that the children eat so much of it they all get sick, and can't bear the sight of it on the table, "and wife and I don't like it so well as we did." Eating honey, with some people, is like eating quails. You soon get satisfied, and no more goes down. In relation to comb honey at 10 cts. per lb., I was informed that a large producer sold his honey at so near 10 cts. that, after taking out expenses of shipping, etc., I was safe in saying 10 cts.; furthermore, dealers in New York quoted me comb honey at 12½ cts. Now take out commission, freightage, and breakage, and how much are you above 10 cts.?

These low prices are facts we have got to face. You say you would give 5 cts. for any quantity. Perhaps you are so fortunate as to receive cash orders from remote points, and can afford to sell your honey thus; but we haven't all got that wide reputation, and we find it costs money to get it.

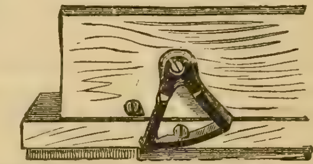
Hartford, N. Y., Feb. 24, 1886. J. H. MARTIN.

Your facts are somewhat discouraging, friend M.; but even if facts are stubborn things, I suppose it is good to have them. Will friends France and Coggshall, who make honey-extracting a business on a large scale, tell us if their honey does not net them more than 5 cts.? When I spoke of the price 5 cts., I supposed you meant that you sold it at that figure, and were obliged to furnish barrels, and deliver it besides. Probably the grocer in that town of 10,000 inhabitants sold only a very small part of the honey retailed in that town; and if other grocers sold as much as he did, it might not be such a very bad showing, after all. It seems to me that the fact that he sold all except two of the largest pails would be a fair indication that it would pay to give him another supply.

THE VANDEUSEN CLASP,

FOR FASTENING STORIES TOGETHER, FOR FASTENING MOVABLE BOTTOM-BOARDS, ETC.

BOTTOM-BOARDS nailed fast, or bottom boards loose from the hive, have been discussed and argued over until the question has been dropped by mutual consent—one party declaring they never wanted another loose bottom-board in the apiary, and almost as many declaring they never want a hive with the bottom-board nailed fast. To accommodate both parties, one of our veteran bee-friends, Mr. C. C. Vandeusen, of Sprout Brook, N. Y., some years ago invented the device figured below.



THE VANDEUSEN CLASP AS IT APPEARS ATTACHED TO A HIVE, CLASPING THE BOTTOM-BOARD.

Little hooks, made of malleable iron, have been used for this purpose, so arranged as to catch on two screws; but these are objectionable, because there is not sufficient power to them, unless made very heavy, and also because they are not conveniently hooked or unhooked when you are in a hurry. The device shown above possesses great strength because the point of the hook is held by a projecting arm of the iron. This projecting arm is arched over so it can not hit against the screw-head. This arch also serves as a projecton to strike against when you wish to draw the clasp up tighter, or to release it. On the opposite corner a similar projection answers the same purpose. If you can not get hold of a stone or piece of brick to drive them off or on, you can almost always make your boot-heel hit one projection or the other; and the machine is so stout that there is no danger of breaking it. Since iron has come down in price, we are now enabled to sell these clasps for 2 cts. each, with a couple of strong screws included. In lots of ten, 18 cts.; or 100, $1.50. If wanted by mail, the postage will be 2 cts. each extra. Where you want 1000 clasps, without screws, we can furnish them for an even $10.00, or at a cost of only 1 cent each.

HUMBUGS AND SWINDLES

PERTAINING TO BEE CULTURE.

We respectfully solicit the aid of our friends in conducting this department, and would consider it a favor to have them send us all circulars that have a deceptive appearance. The greatest care will be at all times maintained to prevent injustice being done any one.

N. C. MITCHELL, AGAIN.

FRIEND ROOT:—Do you know any thing about the National Bee-way Co., with N. C. Mitchell for manager? He gave a lecture here the other evening, and wants to introduce his house here. It is patented. He wants to sell rights to use, etc. I should like information.

Plymouth, Richland Co., O. JOHN EDWIN.

Friend E., you are evidently not conversant with our back volumes, or you would have known that N. C. Mitchell has been advertised as a fraud and swindler for years together. For some time past, however, we have heard little about him; but of late I have had several notices that he was at work around Cincinnati. Do not, under any circumstances, pay him any money. He is not in accordance with modern bee-keeping, and any money sent to him, or given to him, is lost. Some years ago I told the friends that it was like pouring water into a tunnel. The money is gone as soon as it is out of your hands, and you have nothing in the way of an equivalent, and no means of getting it back.

BLUEBERRY-PLANTS AND DELOS STAPLES.

I bought 500 blueberry-plants of D. Staples, Michigan, last year, and have none left to tell the tale, although carefully set. The plants looked like huckleberry-bushes pulled up in some swamp, that were three or four years old, and from 4 in. to 18 in. high. I think he is a fraud. C. A. HATCH.

Ithaca, Wis., Mar. 22, 1886.

In reply to your inquiries about blueberry-plants, we would say that we purchased one dozen from Delos Staples. They were sent by mail, and when received they were as dry as last year's pea-brush. They had neither oiled paper nor moss around them, but were wrapped in a piece of old newspaper. We made up our minds that he belonged to that great army of frauds our country is cursed with, and did not care to waste a postage-stamp writing about the matter. A. H. & G. B. WORTHEN.

Warsaw, Ill., March 20, 1886.

At the time Mr. Staples first advertised blueberry-plants in our journal, we ordered some for our own use. They were simply dry sticks, with scarcely any thing on them that could be called a root. I wrote to him, remonstrating. He said they would grow, even if they had no roots. By great care and sufficient watering, we got a little start on a few of the sticks; but, with all our care, none of them lived. In the first place, it is preposterous to call *dry brush* "plants." The reason I asked for reports from others was because I wanted to see whether that was his fashion of doing business. The above letters, it seems, settle the matter sufficiently. If the friends will tell us what they paid for their plants, we will pay them back their money; and, inasmuch as Mr. Staples has advertised blueberry-plants quite extensively through all of our agricultural papers, I would ask that he be as widely advertised as a humbug and swindler. Several of our agricultural papers have already published him as above, and that is what called my attention to the matter. I very much *doubt* whether blueberry-plants will grow on *any* soil, as he asserts, even if good strong plants with roots were furnished. Will our nursery friends please say if I am not right?

THE GREAT "ACME PENETRATIVE," FOR BURNING STUMPS, ONCE MORE.

We copy the following from the *American Agriculturist:*

> Subscribers are receiving a glowing circular printed on blue paper, describing the virtues of the "Great Acme Penetrative," of New Carlisle, Ohio. The circular sets forth, that "this penetrative actually burns stumps," and "good, honest agents are wanted." Then follows a long list of indorsements from people who have used the Great Acme Penetrative; but, unfortunately for Messrs F. E. Fross & Co., of New Carlisle, who claim to manufacture this penetrative, they have forgotton to give the postoffice address of a single individual who indorses their combustible.

The friends will notice that it is much in line with what we said on page 44, in our issue for Jan. 15, 1886. This F. E. Fross has also been offering seed-corn, possessing remarkable virtues. Many of our agricultural papers have advertised the corn. Fross claims that he offers the seed at a price that would pay only for the packing and postage, in his zeal to have farmers test it throughout the different parts of the country; but complaints have become so numerous, saying that that he never sent any corn at all, that the editors receiving his advertisements have been obliged to apologize for them. We have private advices, saying that the corn he has advertised so extensively was purchased by him out of the farmers' cribs, anywhere he could find it in his own vicinity. Will our agricultural friends please pass him around until he discovers that the way of the transgressor is hard?

FOR SALE CHEAP.

Having bought an interest in A. F. Stauffer's supply establishment, to which I will devote my entire time, I will sell my apiary of

50 Colonies of Hybrid Bees, Cheap.

For further particulars, address
7-9db J. G. SEIDEL, Sterling, Illinois.

EXCHANGE DEPARTMENT.

Notices will be inserted under this head at one-half our usual rates. All ad's intended for this department must not exceed 5 lines, and you must SAY you want your ad. in this department, or we will not be responsible for any error. You can have the notice as many lines as you please; but all over five lines will cost you according to our regular rates.

WANTED.—To exchange or sell a few sittings of Mammoth Bronze turkey eggs, $400 per 13; Partridge Cochin, $2.00 per 13. Also 20 swarms of bees in chaff hives, or exchange for beeswax at 25c per lb. See ad. March 15. 7d
L. GORTON, Salem, Washtenaw Co., Mich.

WANTED.—To exchange iron shafting, nearly new, 7½ feet long by 1⅝ inches., with 2 collars and 3 pullies, 8, 10, and 16 inch; also 3 four-inch boxes, babbitted to fit shaft; one shaft 2 ft. 9 in. long by 1⅞ in., with 10-inch crank arm, and 26-in. pully with 2 six-inch boxes, babbitted to fit shaft, for Italian queens in June, or offers. 7d
F. D. WOOLVER, Munnsville, Mad. Co., N. Y.

WANTED.—To exchange Brown Leghorn eggs, for hatching, for light comb foundation. 7-9d
C. M. GOODSPEED, Thorn Hill, N. Y.

WANTED.—To exchange bees and queens for thoroughbred poultry, P. China and Chester W. Pigs, Simplicity and chaff hives, etc. Address
7-9d JNO. W. MARTIN,
Greenwood Depot, Alb. Co., Va.

WANTED. — To exchange apple, peach, pear, cherry, and plum trees, small evergreens, grapevines, raspberry, blackberry, and strawberry plants, flowering shrubs, vines, etc.; also a lot of Simplicity hives in the flat, or made up, with frames complete. I will exchange for bees, beeswax, section boxes, a Barnes foot-power saw, etc. 7d
D. G. EDMISTON, Nurseryman,
Adrian, Lenawee Co., Mich.

WANTED.— To exchange Simplicity hives or shipping and retailing cases for comb-fdn. machine, G. A. FARRAND,
7d Rockport, Cuyahoga Co., O.

WANTED.—To exchange bees for a Barnes saw, foundation-mill, or Light Brahma fowls; or I will sell bees by the pound; also queens in season.
James P. Sterritt,
5-6-7-8d Sheakleyville, Mercer Co., Pa.

WANTED.—To exchange new Novice honey-extractors for A. and L. frames; will exchange for a bone-grinder, or good books, or any thing useful. Geo. W. Baker, Milton, Ind. 3-5-7-9-11-13d

WANTED.—To exchange or sell. *Eggs for hatching*, from 3 varieties of high-class fowls, selected stock, costing from $12 to $20 per pair. Brown Leghorns, Silver-Spangled Hamburgs, and Plymouth Rocks. Eggs, per setting of 13, $2.00. Safe delivery and a fair hatch guaranteed. (Will exchange for beeswax delivered here at 25c per lb.) Circulars of bees and poultry free. Five settings of Brown Leghorn eggs for $5. Address
6tfdb A. H. Duff, Creighton, Guern. Co., O.

WANTED.—To exchange eggs from standard pedigreed and registered White and Brown Leghorns of the celebrated Smith and Bonney strains, for bees, queens, and supplies.
6-7d L. J. McNaughton, Chardon, Geauga Co., O.

WANTED.—To exchange foundation for wax.
59db B. Chase, Earlville, Madison Co., N. Y.

WANTED.—To exchange nursery stock, especially evergreens, for Italian bees, queens, and two-frame nucleus with Italian bees and queen.
678d R. A. Lewis, Cherokee, Iowa.

WANTED.—To exchange. I have a complete printing-office, consisting of 20 fonts of general job type, nearly new, some never used; 18 lbs. brevier, for circular work, all in job cases and cabinet; one Cottage hand cylinder-press, 6x10 chase, one Novelty press, 10x14 chase; composing-stick, rules, leads, etc. Cost over $200. I will take fdn., sections, cash, or other goods. Make an offer.
6tfdb E. Kretchmer, Coburg, Iowa.

WYANDOTTE and Houdan cockerels; good birds at low prices, to close out surplus; also one *White Wyandotte* cockerel; or I will exchange for white extracted honey. Eggs for hatching, $2.50 and $1.50 per 13. J. Evans,
6-7 Box 89, Schaghticoke, Rens. Co., N. Y.

WANTED.—To exchange, Simplicity or other hives for good section or extracted honey. Will sell hives (in the flat) cheap for cash, or will take one-third pay in full colonies of bees, or poultry. Hives in any quantity to suit customers, up to a car-load per day. G. A. Farrand,
3tfdb Rockport, Cuy. Co., Ohio.

WANTED.—To exchange Italian bees, brood, and queens, for fdn., beeswax, type-writer, or any thing having a standard market value. 6tfdb
Thomas Horn, Box 691, Sherburne, Chen. Co., N. Y.

WANTED.—To exchange white-poplar sections, sandpapered on both sides, or any kind of bee-keepers' supplies, for comb or extracted honey. Send 5c. for sample section; 50-page circular free.
6-7d J. B. Mason & Sons,
Mechanic Falls, Androscoggin Co., Me.

WANTED.—To exchange one W. Moore & Co.'s double-barreled breach-loading shot-gun (rebounding-bar locks, good as new), and one silver hunting-case watch, nearly new (Columbus Watch Mfg. Co.'s make) for foot-power saw, bee-keepers' supplies, or choice poultry or Italian bees.
6tfdb J. A. Bucklew, Clarks, Ohio.

WANTED.—To exchange for a farm, or sell my place, consisting of 7½ acres of ground in the town of Lewisville, Ind. A small dwelling, poultry-houses, stable, and an everlasting gravel-bank, which affords about 3000 loads of gravel every year, which sells readily at from 10 to 15 cts. per load. The place is in a good honey locality, and good shipping facilities. Apiary slopes to the south and east; is surrounded on the north and west by a tight plank fence, about 7 ft. high. Apiary is set in grapevines. I will give five years' time, if sold. Direct all communications to
3-5-7d Geo. W. Baker, Milton, Ind.

WANTED.—To exchange apiarian supplies at any time, or nuclei in June, for extracted honey, extractor, or foundation-mill. Circulars free.
67d C. P. Bish, Petrolia, Butler Co., Pa.

WANTED.—To exchange S. C. Brown Leghorn eggs or P. Rocks of pure breed for Pekin Duck eggs or other eggs of pure-bred fowls; also for sale, $1.00 for 15, 36 for $2.00. David Lucas, Jewett, O.

WANTED.—To sell or exchange, farm, 180 acres, good buildings, good sandy soil; also latest improved Steam Thrashing-machine. Either or both at a bargain. Address J. A. Osbun & Son,
7tfdb Spring Bluff, Adams Co., Wis.

WANTED.—To exchange for bees, or to sell, 15,000 Cuthbert raspberry-plants ar 75 cents per 100, $5.00 per 1000. They are nice plants, true to name. Remit by reg. letter. Address
7d P. D. Miller, Grapeville, Westm'd Co., Pa.

WANTED.—To exchange 12 Brown Leghorn pullets, 10 Plymouth Rock pullets, 1 trio S. S. Hamburgs, 1 Wyandotte cockerel, eggs from P. Rocks, Wyandottes, Light Brahmas, S. S. Hamburgs, Brown or White Leghorns, for Barnes foot-power buzz-saw, Novice honey-extractor, and saw-mandrel. Cash or offers. Adolphus Newton,
7d Plymouth, Chenango Co., N.Y.

WANTED.—To exchange Carniolan and Italian queens or bees, for pure-bred Brown Leghorn (Bonney's Strain), and Wyandotte eggs, for hatching. Send for circular. Chas. D. Duvall,
7tfdb Spencerville, Mont. Co., Md.

WANTED.—To exchange about 50 or 60 good Plymouth Rock and Light-Brahma fowls for apiarian supplies, or 9 hens and one cockerel for $5.00, cash preferred. Julius Johannsen,
7d Port Clinton, Ottawa Co., Ohio.

WANTED.—To exchange pure Italian queens for beeswax at 28c per lb. Queens, select, $3.00; warranted, $1.50. Ship wax by freight to Barrytown, N. Y. Cornelius Bros.,
7 11 db LaFayetteville, Dutchess Co., N. Y.

WANTED.—To exchange 800 empty combs (nearly all wired fdn.), L. or Simplicity size, and 100 Simplicity hives (50 covers, 50 bottom-boards (all well painted, for basswood or white-clover honey, to be delivered next fall, combs and hives ready to ship now. Write for particulars.
E. T. Flanagan,
7 8d Box 995, Belleville, St. Clair Co., Ill.
P. S.—Will exchange 200 lbs. sweet-clover seed for honey or raspberry-plants.

WANTED.—To sell or exchange, pure S. C. Brown Leghorn eggs at 75 cents per 13, for beeswax, or books of poetry or history.
7-8d Mrs. Alice Bright, Mazeppa, Minn.

WANTED.—To exchange 13 Plymouth-Rock eggs for 75 cts. in cash; securely packed, and warranted pure. Orders filled at once. 7d
MRS. C. E. HATCH, Kentland, Newton Co., Ind.

WANTED.—To sell or exchange Hoags' hand-planter for corn, beans, etc. @ $2.50 cash, or $3.00 in trade. Satisfaction guaranteed, or money refunded. S. hives in the flat taken.

WANTED.—To sell cheap, or exchange, a 5×7-inch printing-press, type, etc., for early nuclei, queens, or full colonies. Write at once, as it is in my way, and I am anxious to dispose of it.
7d C. Weckesser, Marshallville, Wayne Co., O.

WANTED.—To exchange, rabbits or Wyandotte fowls, or their eggs, for Gregg raspberry-plants. A. A. Fradenburg,
7d Port Washington, O.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

HONEY AND BEESWAX.

Our market, and location as a trade center, the rapid growth of our city and country, gives us a large demand for honey. We have found it impossible to keep a stock of 1-lb. frames, unglassed, and of which we are in need. This style of comb sells much faster than any other and we will make liberal offers on receipt of samples. We are well stocked on 2-lb. sections, also extracted. Beeswax wanted on commission. **CLEMONS, CLOON & CO.,**
15-7b KANSAS CITY, MO.

100 Colonies of Bees for Sale!

My 650 colonies of bees are more than I can well handle, and I will sell 100 full colonies at $5.00 each for hybrids, $6.00 for pure Italians. Discount on larger numbers. I will also sell a few colonies of Caucasian bees, which breed I imported from the Caucasus Mountains, Asia, in 1880, and have found them of great value to me. Address

KIND WORDS FROM OUR CUSTOMERS.

In order to supplement the offer of a nucleus of bees, I think it was, to largest club-raiser for GLEANINGS, I offer an "Ideal glass-front bee-veil."
St. Albans, W. Va., Apr. 6, 1886. J. C. CAPEHART.

GLEANINGS AS AN ADVERTISING MEDIUM.

My advertisement in GLEANINGS has brought me more letters than any paper I ever advertised in, and that is over two hundred. W. J. HESSER.
Plattsmouth, Neb., March 29, 1886.

GLEANINGS "SEMPER IDEM."

I like all of GLEANINGS, and when I like a thing I'm not going to pull it all to pieces. I think GLEANINGS is put together just as well as I could do it, and it is GLEANINGS every time. Sometimes I do not see a number of *Harper's Monthly* for years; but when I do see one it is *Harper's* or nothing else, and GLEANINGS is the same way.
MAHALA B. CHADDOCK.
Vermont, Ill., April 3, 1886.

KIND WORDS FOR ERNEST.

What excellent work Ernest is doing on GLEANINGS! Perhaps you haven't noticed it, but I *have*, and I feel like congratulating both you and him.
W. Z. HUTCHINSON.
Rogersville, Genesee Co., Mich., Mar. 23, 1886.

[Thanks, friend Hutchinson, for your very kind words. If I have merited any encouragement from one of the old veterans, I shall be happy to continue in this work; for I have sometimes felt as if I ought to keep still till I "growed" a little more in apicultural learning.] ERNEST.

SOME PLEASED CUSTOMERS, ETC.

The hives, etc., ordered of you Feb. 27, arrived the 1st inst., and were unpacked to-day, and I delivered those ordered for my neighbors. Pleased? I should say they were. You ought to have seen that smile on their faces when they saw those tin covers. They are far ahead of what we have been getting. Every thing is here — nothing missing. They cost us a little more than the Louisiana hives, on account of the longer distance; but they *suit me* better, and I expect to patronize you hereafter.

My bees are very strong in numbers, and have plenty of stores, and are also getting a good deal of honey from redbud and haw; also apple-bloom. Bees are beginning to swarm some in the neighborhood. A. P. WRIGHT.
Reagan, Falls Co., Texas, April 3, 1886.

SYRIAN AND ITALIAN QUEENS,

Before June 15, tested, $2.50 each; after, $2.00 each. Untested, before June 15, $1.00 each; after, single queen, $1.00; six for $5.00; twelve for $9.00.

ADMINISTRATOR'S SALE.

The undersigned will sell at public auction, at premises of F. E. Townsend, deceased, the following described property, on Wednesday, April 28, 1886: About 75 colonies of Italian bees, mostly in double-walled chaff hives, Gallup frames, 11x11¼, and in good condition. About 50 single-walled hives, and frames of empty combs, in No. 1 condition; 1 new comb-foundation mill; uncapping-stand; smokers, 10 crates and sections, and other articles used in the bee-business, too numerous to mention.

Also offered for sale, 40 acres of choice land, 3 acres cleared, rest good timber; new frame two-story house, 16x24, finished outside, and primed, ready for plastering inside; drive well and pump in house. Situated 8 miles southwest of Ithaca, County-seat of Gratiot Co., Mich. This locality can not be equalled in the State for bee-business. Above property is subject to private sale before commencement of auction. For particulars, address

Black and Hybrid Queens For Sale.

For the benefit of friends who have black or hybrid queens which they want to dispose of, we will insert notices free of charge, as below. We do this because there is hardly value enough to these queens to pay for buying them up and keeping them in stock; and yet it is oftentimes quite an accommodation to those who can not afford higher-priced ones.

I have a few black queens for sale at 25 cts. each. Ready by May 5th. T. L. REES,
Winchester, Adams Co., Ohio.

I shall re-queen my whole apiary this year, and will sell black and hybrid queens at 25 and 50 cents each, from May 1st. D. A. FULLER,
Cherry Valley, Winnebago Co., Ill.

100 black and hybrid queens for sale at 30 and 40 cts. each, all clipped. Address L. T. AYRES,
Kankakee, Kankakee Co., Ill.

Black and hybrid queens for sale at the usual rates. GEO. D. RAUDENBUSH,
Reading, Pa.

FOR SALE.—8 young mismated Italian queens. Ready now. MISS A. M. TAYLOR,
Mulberry Grove, Bond Co., Ill.

50 Colonies of
Italian Bees For Sale,

In shipping-box, 7 L. frames, tested queen, per colony $6 00
4-frame nucleus, tested queen 3 00
" " " untested queen 2 50
Safe arrival guaranteed.
7-10db **TOM PHELPS, Sonora, Ky.**

WANTED SITUATION IN AN APIARY. Salary reasonable. Satisfaction guaranteed. Address WESLEY BALDUFF,
April 10. 8d Milford, Iroquois Co., Ill.

HONEY COLUMN.

CITY MARKETS.

NEW YORK.—*Honey.*—We note an improvement in sales of comb honey the past two weeks; and owing to the lateness of the season, prices rule low. In consequence of the low rates of freight from San Francisco to New York, many dealers in honey are taking advantage of the rates, and shipping extracted honey to this market at prices ranging from 4½@5½c per lb. This has already had its effect on State goods. We quote prices as follows:

Fancy white comb honey, 1-lb. sections,	12@13c
" " " " 2-lb. "	9@10c
" buckwheat " 1-lb. "	9c
" " " 2-lb. "	7@8c
Off grades, 1@2c per lb. less.	
Extracted white-clover,	6@7c
" buckwheat,	5@5½
" California,	5@6c
" Southern, as to color and flavor, per gallon,	50@60c

April 6, 1886. McCAUL & HILDRETH BROS.,
34 Hudson St., cor. Duane St., New York.

CHICAGO.—*Honey.*—Market active this month, but prices are easier, 16 cents being the very outside for white comb; extracted, without much change. *Beeswax* steady at 25 cts. per lb. Market brisk all around.
R. A. BURNETT,
April 10, 1886. 161 S. Water St., Chicago, Ill.

CLEVELAND.—*Honey.*—The market is bare of new 1-lb. sections, and in consequence the 2-lbs. begin to move a little; also, for want of new the old 1-lbs. are moving at 8@to9c. Best 1-lb. new white would sell readily at 14@15c; 2-lbs., 12@13c. Extracted, 7c. *Beeswax*, scarce at 25@28c. A. C. KENDEL,
April 20, 1886. 115 Ontario St., Cleveland, Ohio.

MILWAUKEE.—*Honey.*—The supply of choice honey of any sort continues quite small, and shipments of either comb or extracted will find a sweet reception. We can quote choice 1-lb. sections, white, at 16@18c; 2-lbs., 15@16c. Dark honey not wanted. Extracted, white, in kegs or bbls., 7½@8½c; good dark, do., 6@6½c. *Beeswax* wanted; 25 cts. for yellow.
April 10, 1886. A. V. BISHOP,
142 W. Water St., Milwaukee, Wis.

CONVENTION NOTICES.

The Western N. Y. and Northern Pa. Bee-keepers' Association will hold their next annual meeting at Randolph, N. Y., May 4, 1886. A. D. JACOBS, Sec., Jamestown, N. Y.

The semi-annual meeting of the Progressive Bee-keepers' Association will be held at Grange Hall, Bedford, O., on Thursday, May 6, 1886, at 10 o'clock A. M.
Bedford, Cuyahoga Co., O. MISS DEMA BENNETT, Sec.

Linwood Bee-Keepers' Association will be held in Condit's Hall, Rock Elm, Wis., Saturday, May 1, 1886, at 1 o'clock P.M. All interested in bee-keeping are cordialy invited to attend and make the meeting a profitable one. B. J. THOMPSON, Sec.

The Annual Meeting of the Northern Ohio Bee-keepers' Association will be held in the New Town-Hall at Wellington, Ohio, Friday, April 30, 1886. All are invited to come and help make the meeting both pleasant and profitable. A special invitation is extended to the ladies. The officers of the Association will be elected at this meeting. H. R. BOARDMAN, Sec.
East Townsend, Ohio, April 6, 1886.

The Keystone Bee-keepers' Association will meet at Court-House in Scranton, Pa., on Tuesday, May 11, 1886, to elect officers, transact important business, and listen to the able papers of Messrs. G. M. Doolittle on the production of comb honey; L. C. Root on the production of extracted honey, and the Dadants on queen-rearing and general management. Come one and all, and make this meeting the best of all.
Clark's Green, Pa., Apr. 2, 1886. ARTHUR A. DAVIS, Sec.

The Western Bee-Keepers' Association will meet in Pythian Hall, N. W. cor. 11th and Main Sts., entrance on 11th, Kansas City, Mo., Apr. 29, 30, 1886. Parties can take the Cable line at Union Depot for 9th and Main Sts.

The following essays will be read:

"The Honey Market," Clemons, Cloon & Co., Kansas City, Mo.
"Bee-keeping in Iowa," E. Kretchmer, Coburg, Iowa.
"Best Method of Handling Bees for Comb Honey," A. A. Baldwin, Independence, Mo.
"Missouri Bee-keeping," I. D. Pearce, Kirksville, Mo.
"Does Bee-keeping pay as a Pursuit?" Jos. Nysewander, Des Moines, Iowa.
"Invertible Frames and Hives," J. M. Shuck, Des Moines, Iowa.
P. BALDWIN, Sec.
Independence, Jackson Co., Mo.

CIRCULARS RECEIVED.

The following have recently sent us their price lists.

J. M. Shuck, Des Moines, Ia., a 32-page, illustrated price list of bee-supplies. Contains much valuable information besides.
H. H. Brown, Light Street, Pa., 18-page list, bees and queens.
John C. Capehart, St. Albans, W. Va., 16-page list of bees and queens.
T. S. Sanford, Bradford, Pa., 8-page list — bee-supplies.
Bright Bros., Mazeppa, Minn., 20-page list, apiarian supplies.
Smith & Smith, Kenton, O., 20-page list, supplies in general.
W. S. Russell, Millbrook, Ont., 12-page circular, bee-supplies.
Joseph E. Sharer, North River, Va., an advertising sheet of apiarian supplies.
Jno. C. Stewart, Hopkins, Mo., a 10-page list — bee-supplies.
J. E. Pryor, Dexter, Ia., a 4-page list — hives a specialty.
T. F. Shepard, Franklin, Pa., 6-page list, apiarian supplies.
C. Weeks, Clifton, Tenn., an advertising card—Italian bees a specialty.
A. E. Woodward, Groome's Corners, N. Y., a 4-page sheet of bees and queens.
J. B. Kline, Topeka, Kan., 4-page price list, poultry and bees.
J. C. Bowman, North Lima, O., a 12-page list, bee-supplies and poultry.
C. M. Goodspeed, Thorn Hill, N. Y., 4-p. sheet, bees and poultry.

The following have had their price lists printed at this office:

G. W. Stanley, Wyoming, N. Y., 6-page price list — specialty, the Stanley Automatic extractor.
Abbott L. Swinson, Goldsboro, N. C., an advertising sheet—bees and queens a specialty.

I am being asked my opinion of the new circulars Mrs. Cotton is again sending out quite plentifully. The statements she makes, and the prices she charges for the goods she sends out, would, in my opinion, forbid her being classed with our regular supply-dealers, to say nothing of the strings of complaints against her that have filled our bee-journals for years past.

1000 Lbs.

BEES FOR SALE.

Here I am for the spring of 1886, with **1000 LBS. OF HYBRID BEES** for sale by the pound. Bees $1.00, and queens 50 cts. in May; bees $1.00 and queens 35 cts., after the 10th of June. SHALL WE SHIP OUR HONEY IN SECOND-HAND WHISKY-BARRELS?

DOES IT DAMAGE THE TRADE BY SO DOING?

I HAVE looked for a long time in several of the bee-journals for information regarding shipping extracted honey by the barrel. I have seen but one article in a bee-journal, and that was in the *American Bee Journal* during Aug., 1884, and the pamphlet of the Messrs. Dadant on "Extracted Honey." Both of the before-mentioned articles, from Messrs. Muth and Dadant respectively, are not explicit enough for the beginner, and are misleading besides.

Not being able to profit by the experience of others, I was forced to enter the dear school of personal experience the past year, and learn for myself. I haven't Mr. Muth's article at hand, and can not state its points correctly; but Mr. Dadant's pamphlet, on page 13, says: "The barrels that we use for extracted honey are oak barrels which have contained alcohol or whisky. We allow them to dry up thoroughly before using, and wet them only slightly when putting up the honey." This was my main guide during the past season, except I did not "wet them slightly." I allowed the whole and half whisky-barrels to stand in the shade, and dry till the hoops would fall off when I moved them. As I needed them I drove the hoops as tightly as I could drive them. Occasionally I would burst a hoop off in driving it. Then I put in my honey, bunged the barrels up, and rolled them under the house. In two weeks the hoops would be so loose that the honey would be oozing out all around the barrels, and the cracks would be covered with bees.

When I re-coopered them I was able to drive the hoops (except the end hoops) from ¼ to ½ an inch each time.

Last April I sent 4½ barrels of white-clover honey to Mr. C. F. Muth, Cincinnati, O., first having to re-drive the hoops after hauling to the landing. I wrote to Mr. Muth, asking his opinion as to quality. He answered, "It is of good quality, but does not come up to our Northern clover-honey." Why? The probable reason will appear later on. He gave me 5 cts. a pound for it.

In June I sent seven barrels of white-clover honey to McCaul & Hildreth Bros., New York, in what I thought perfect order. The barrels were dry as bones; coopered as tightly as hammer and steel edge could drive them before loading to take to the landing; re-driven after unloading at the landing, and I had perfect confidence that they were in perfect condition, both as to quality of honey inside the barrels, and cooperage on the outside the barrel. In a couple of weeks I received a letter from McC. & H. Bros., in which they said that the honey arrived in bad order, and was leaking badly; that they had to have the barrels re-coopered on the wharf, and again when they were unloaded at the store. They charged me $1.75 for cooperage, and rendered me an account sales at 55 cents per gallon. The rest of my honey was dark.

Now, Mr. Root, what was the cause of such low prices for white-clover honey? I wrote to a Chicago commission merchant concerning the future honey market, and he replied as follows:—"If your honey is free from the odor of that which comes in Southern honey generally, I don't know of any reason why it will not grade with our Northern white clover."

Where does this "odor" come from, that depreciates the price of Southern honey? A druggist here told me a short time since that the smell of a whisky-barrel would taint honey, and I am fully prepared to accept it as truth. My average price for honey the past year, above freight, etc., was 4½ cts. per pound; 11½ barrels were white clover, and 9½ dark. That seems to me a very poor price for honey. My reason for it is, that the whisky-barrels ruined the quality of the honey. If this is true, it will be in keeping with the fact that whisky ruins the quality of about every thing it comes in contact with, especially the human kind. I am done shipping white-clover honey in stinking whisky-barrels, which cost 75 cents, while I can get brand-new cypress molasses-barrels for $1.10, or second-hand molasses-barrels in good order, free on board, for 75 cents. I have no doubt that much of the honey that helps to injure the market is caused by such doings as mine last year—shipping fine honey in stinking barrels that are fit for nothing but firewood. I venture to say, that a whisky-barrel will taint honey enough to depreciate its value at least one cent per pound; and if so, that would be a money loss of about $5.00 a barrel. If this be so, is not a whisky-barrel, which seems cheap at 75 cents, but which causes a loss of over $4.00 a barrel, besides causing slow sales, the very costliest barrel possible to find? I have just laid in ten cypress (second-hand) molasses-barrels re-coopered, in fine order, for 75 cents apiece, and I shall henceforth have no further use for whisky-barrels for honey.

This matter cost me a great deal this past season to learn about, and I wish you would give your ideas concerning packing honey in hard-wood second-hand whisky-barrels. This whole Mississippi-River country is a great honey country and *saloon* country, and whisky-barrels are used because presumably cheap. Please help to put that kind of package under condemnation. C. M. HIGGINS.

Hahnville, La., Mar. 4, 1886.

Many thanks, friend H., for your very valuable, practical article. Some years ago we put up some honey in whisky-barrels; and although they were not waxed we never had any complaint on that score, that I know of. Now, are you not afraid that you will have your honey tainted more or less by barrels of any kind? I should be very much afraid of the second-hand molasses-barrels you speak of, unless they are very thoroughly washed, and then waxed; and I have a sort of notion that wood may taint honey, even in spite of waxing; that is, I have been better pleased with the flavor of white-clover honey that was run right into iron-jacket cans, tin sap-pails, or tin storage cans, than when put into any kind of wooden receptacle. The package illustrated on page 274 of last issue, it seems to me, is going to be pretty nearly what is wanted, when we settle down to a regular package for honey.—In regard to the flavor of white-clover honey that comes from the South, I confess I have never seen any samples of Southern honey that didn't have a peculiar flavor, a little different from the white-clover honey of, say, Ohio, York State, Michigan, and Wisconsin. I have sometimes thought there might be some particular honey-bearing plant in the South that blooms about the time of white-clover, and that it was so prevalent that the honey partook of the flavor, more or less. I believe friend Muth considers, as a rule, Southern honey not quite as desirable as that from the North; that is, there are more people who prefer the peculiar flavor of the honey from the Northern States than any other kind that has been put on the market. Even the finest specimens of basswood honey now begin to be quoted at one cent lower than clover.

HEDDON'S INVENTION.

SOME CORRECTIONS.

BRO. ROOT:—I accept your offer of a "wee" space to correct the false impression made by the use of several columns and cuts illustrating my invention. I inclose you a copy of Mr. Kretchmer's patent, cited in his article on p. 211. Now, you see that Mr. K. is deceiving your readers, for there is not one feature in the construction or purpose of his old hive that anticipates any feature or function of mine—*not one.* The brood-chamber is *not* in two divisible parts; it can *not* be divided, alternated, nor inverted; neither can the surplus-apartment be inverted. The purpose of his invention, as set forth in his four declarations, is entirely foreign to mine. Why do our brothers wish to wrong me in this way? I call your attention to the fact, that, in the last issue of the *A. B. J.*, page 200, Dr. Tinker concedes the hive he described in your paper, pages 203, '4, '5, as coming under my invention. JAMES HEDDON.

Dowagiac, Mich.

We notice, in comparing friend Kretchmer's article on page 211 with his patent-claim, the *last clause* is not to be found anywhere in said claim. We have written to him for an explanation.

KIND WORDS FROM PROF. COOK; HEDDON'S NEW HIVE, ETC.

"RENDER UNTO CÆSAR THE THINGS THAT ARE CÆSAR'S."

DEAR MR. EDITOR:—I need not tell you how highly I appreciate GLEANINGS, and of the pleasure which it has ever given me to note the progress which you have made in building up a journal which has taken fast hold of the affections of our bee-keeping public. GLEANINGS deserves to be what it is—a tremendous force in the country. It has reached out in every way that it could to promote the welfare of its patrons, and has certainly greatly aided its readers in the hard matters of busy, practical, every-day life, and, better still, helped them on to nobler, better lives. Hence you will not wonder that I am grieved when I see it taking what looks to me to be a backward step, aiding wrong, and abetting that spirit—too rife among us—of dishonesty where it is safe. It seems to me that stealing melons is no less a sin because community will condone it. Genuine honesty will not cheat in a horse-trade because it is reputed common.

Now, my friend, we have all known you too long to even dream that you are intentionally doing wrong or injustice; so if, as I fear, you are in this one case aiding injustice and helping to make men less scrupulous of others' rights, you would, when convinced, feel more keenly the error than would any other person.

I believe most sincerely, as I believe nine-tenths of the intelligent bee-keepers of the United States and Canada do, that Mr. Heddon's hive and methods, as given in his new book, are original. Have you, my dear friend, the faintest conception that we should have heard of this hive and system, if Mr. Heddon had not spoken? I don't believe any informed bee-keeper in the United States thinks so. Of course, as yet the value of the invention is a question to most of us; but I can not see how the fact that it is original with Mr. Heddon can be questioned. Now, if I am right, I think I should be just as excusable in taking from your office the money received from GLEANINGS as to make and use the Heddon hive without first securing the right. I have not heard a word from our friend Dr. C. C. Miller on this subject, and I should like him to say in GLEANINGS if he does not utter an amen when he reads the above. I speak of Dr. Miller, because I believe that he is one of the best representatives of a large class—almost all—of our American bee-keepers who love justice as they do life, and who will never consent to see a brother bee-keeper robbed of his rights. A few knaves and a great deal of ignorance robbed our good father Langstroth of his property. GLEANINGS, the *American Bee Journal*, and a host of other potent influences, have so reformed the former and lessened the latter that the thing can not be repeated. Unless I am entirely mistaken in my estimate of the bee-keepers of America, and I don't think I can be, Mr. Heddon's rights, legal and moral, will be kept inviolate in their charge.

R. L. Taylor, of our State, is one of our best bee-keepers, thoroughly informed, is as true, genuine, and honest a man as is Dr. Miller, and, besides these, is a good lawyer. I have not asked his opinion in this case, but I am so sure what he would say that I should be willing to rest the case with him as a judge. Please, Mr. Editor, ask his opinion, for the good of us all.

Now, why I am so earnest in this matter is this: It seems to me our very social atmosphere is dark with dishonest practices. The business maxim often urged, "Treat every man as a knave," is a shame unto us. We are in no danger of becoming too scrupulous in our dealings with men. Let us, then, frown upon all words or acts that even savor of injustice. The work on ethics which I studied in college urged that, if the least doubt as to the morality of an act exists, we should avoid the act. I wish every editor would urge this rule.

A careful inspection of Mr. Kretchmer's patent convinces me that his hive, and the system its use would necessitate, are not Mr. Heddon's at all. Dr. Tinker's words in the *American Bee Journal* are wise and true—"*The hive is original, the system is new.*"

Again, we do no injury in urging all to do justly in this matter. Without Mr. Heddon's book and patent we should have known nothing of his hive and methods, and certainly would not have used them. We need not use them any more now. We owe our opportunity to use them to Mr. Heddon; then surely, if we think them worth adopting, we owe him the small sum asked for the right. That American bee-keepers will concede this fact, and act accordingly, is beyond question.

I am glad that the *American* and *Canadian Bee Journals* are both urging the right course. I feel just as sure that GLEANINGS and its editor will heartily adopt the same course. "Let us be just, though the heavens fall," is a resolve we may all safely make, and urge upon others. I have no doubt or fear of the outcome in this matter; but I am tremendously anxious and desirous that GLEANINGS should teach the most exact justice.

A. J. COOK.

Agricultural College, Mich., April 2, 1886.

Dear friend Cook, I have not the least doubt in the world of the entire sincerity with which you wrote the above; but yet I do think—in fact, I can not think otherwise, than that you are at least just a little mistaken. There are two plain sides to this question, and it seems to me that you are looking unconsciously on only one side. I do not feel as though it were my duty or my place to take sides with either party; but I can honestly and sincerely say this much: If any one who reads Heddon's book feels disposed to follow his plan of working, let him purchase a hive of Heddon, exactly as it should be. After having satisfied himself that he wishes to adopt the plan or principle, either buy all of his hives of Heddon or pay friend H. five dollars (or whatever other price may be agreed upon) for the privilege of making them himself. So far the matter is easy, and we are now on common ground, where we can all agree. When it comes, however, to the nice point of deciding what infringes on friend Heddon's invention and what does not infringe, I beg leave to be excused from trying to decide or even advising. I myself may be prejudiced, and I may look on one side more than on another; but this thing my conscience does tell me most strongly, we are wasting precious moments in what I am sure is not a matter of such very great importance after all; and I am sure it is wrong to take more space for this matter—not only wrong to the great mass of our readers, but a wrong in the sight of God. Can we not drop it here?

LET REASON TAKE THE PLACE OF SUPERSTITION.

A TRIBUTE TO THE WORTH OF THE EXPERIMENTAL STATIONS OF OUR DIFFERENT STATES.

WHEN I have looked over the agricultural papers, especially the papers devoted to poultry-keeping, I have been pained to see the glowing advertisements of packages of some kind of secret compound to "make hens lay," and other things of similar import. Do you ask why I felt pained? Well, I felt pained because it seemed to me so improbable that the advertisement was an honest and truthful one. It is, as it were, on a line with the remedies for bee-stings. Over and over again I have been asked to insert advertisements of bee-sting remedies. A good many times, bottles have been sent to me to test. How do you suppose it has turned out? Why, just as I have told you in the A B C book. When tried fairly, the remedy proved to have no effect whatever. If used thoughtlessly, as people often use things, the verdict would be in favor of the remedy.

They put on some of the medicine, and the pain soon ceases, as it would have done had no medicine been employed. Well, our friends pay 50 cts. for a package of egg food. It is given to the hens according to directions, and the hens begin to lay, just like drumming on tin pans. After you have drummed a while the bees begin to cluster. I have not said any thing about the egg food, because I hadn't time to investigate. Our man who has charge of the horses and cattle bought a package, and I decided in a very few moments, that, even if it were good, it was a swindle to charge 50 cents for it. Please read the following extract, which we clip from the *New-England Farmer* of March 6:

> Prof. W. H. Jordan, Director of the Maine State Experiment Station, reports in a recent bulletin upon the food value of some of the "condimental" foods found in our markets, and arrives at the conclusion that they cost those who purchase them several times their actual worth. The Imperial egg food, costing 50 cents per pound, contained 84 per cent of mineral matter, chiefly ground clam or oyster shells, and a little bone, the rest being water and organic matter; but he found only one per cent of flesh-forming material. Its true value is but a small fraction of the price asked. Poultry-keepers do well to furnish their poultry with abundant supplies of shell or bone, but these can be bought by the hundred pounds at from *one* to *two dollars*, leaving the other *forty-eight dollars* for the dealer's profit. "Johnson's Continental Food," made in Lynn, Mass., and the "English Patent Food" for cattle, which sells at from 7½ to eight cents per pound, were found to be composed chiefly of wheat bran and corn meal, with a trifle of fengreek, an aromatic seed, and a little sulphur, neither of which is of any value to healthy animals, nor of any reliance for curing sick ones. Neither of the foods have any greater nutritive value than the bran or corn meal from which they are made. But there is a mystery in the minds of most persons concerning all substances that are claimed as having medicinal properties, and so the exorbitant prices are paid quite cheerfully, The experiment stations are doing good work when they clear away the mists from before the eyes of the working and debt-paying classes.

Now, friends, it may be that this egg food contains some stimulant for poultry, such as cayenne pepper, or something of that sort; and it is also possible that the combination of substances is of value in stimulating the hens to lay; but, why charge 50 cts. a pound for something that could be sold at a profit for 5 cts. a pound? Is it fair or right? and ought any one who professes to be a Christian to engage in any such kind of business? I think we can safely say, "Thank God for this new era of experimental stations, kept up by the States."

BLUEBERRY - PLANTS AND DELOS STAPLES.

THE OHIO AGRICULTURAL - EXPERIMENT STATION NOW TAKES THE MATTER IN HAND.

I THINK you are right in exposing Delos Staples. Blueberry-plants such as he sends *will not grow* on upland soil. I ordered some of him two years ago, supposing from his advertisement and the letter he wrote me, that he had improved the upland species; but the plants he sent evidently came from a swamp, and had but very little root. They were also packed very poorly, and I knew from experience that no kind of tree or shrub with such poor roots, and so badly dried, would grow; hence I remonstrated with him before paying for them. He wrote me such a penitent letter, agreeing to profit by my suggestions as to packing, also offering to send more plants, that I sent the money. I inclosed a receipt for him to sign, and then had to write several sharp letters, and even threatened to publish him, if it was not returned. The last letter brought the receipt, and more penitential promises, but that is the last that I ever heard from Mr. Staples. I am now persuaded that I ought to have published him. He may not be defrauding intentionally, but surely his method is the same as that practiced by the Bain gang and others. First, you see an article in some unsuspecting newspaper on the blueberry, by Delos Staples; then his advertisement. Furthermore, he gets his bushes from the swamp, and either does not know how, or does not care to know how to pack them. I even agreed to *pay* him for another lot of plants, if he would pack according to my directions, but it seems that he is not anxious to have his plants experimented with.

W. J. GREEN, Horticulturist,
Ohio Experiment Station.

Columbus, O., Apr. 3, 1886.

Friend Green, I am very glad indeed to have your assistance in this matter, and I hope now the agricultural papers at large will give him such publicity as he deserves. It is not alone on blueberry-plants, but in other things that he is taking the part of a swindler. Some years ago, failing to collect an account of him, I ordered potted strawberry-plants; but instead of potted plants he simply sent plants with what seemed to be a ball of mud around the roots. As they were put loosely in a box, the mud was pounded off the greater part of them. But it was almost impossible to get a word from him in regard to the matter; and our experience was eventually about like your own. One who advertises as widely as he does ought to be just as widely exposed. A great number of letters have been received since the notice was put in GLEANINGS, and all tell the same story; viz., dry twigs, no roots, nor suitable packing.

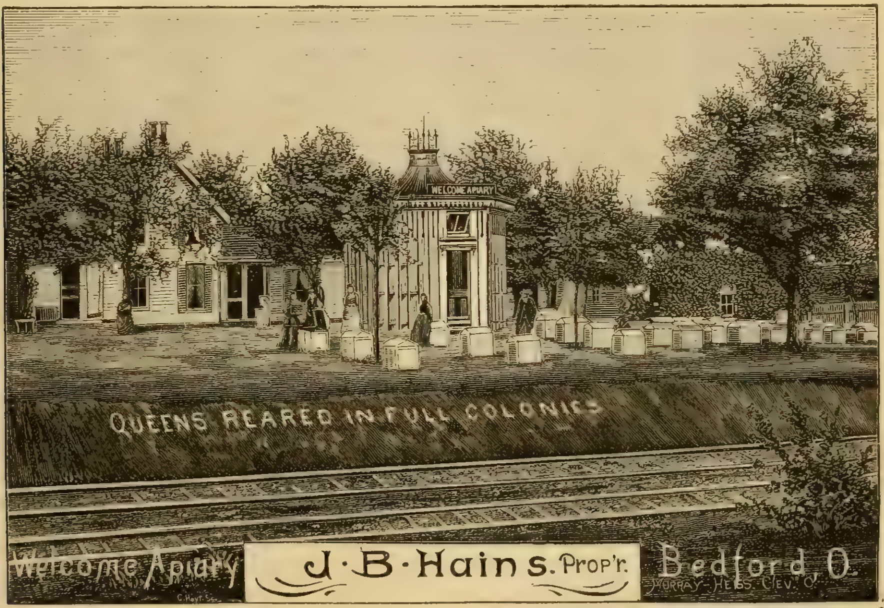
REPORT FROM WELCOME APIARY.

SIXTEEN YEARS OF BEE-KEEPING, AND A PICTURE OF FRIEND HAINES' BEE-YARD.

WELCOME APIARY is located in the village of Bedford, Cuyahoga Co., Ohio, on the Cleveland & Pittsburgh and Cleveland & Canton Railroads, both of which run through it, dividing it about equally—the east half only showing in the above engraving. It may be said to have been established July 4, 1844, when a fugitive swarm of bees clustered on a tree near where the house-apiary now stands. Being eleven years of age, I assisted in hiving and caring for them, and from that time they received box-hive attention—sometimes numbering a score or more, at others only two or three colonies, but never becoming entirely extinct.

In the spring of 1870, there being but three stocks, I transferred and Italianized them, and commenced bee-keeping on modern principles. I have tested nearly every thing said to be an improvement or a help in the business. I have retained only such as proved to be beneficial, among which I may mention movable frames, comb foundatian, honey-extractor, smoker, veil, slow feeder for spring and rapid feeder for fall, division-boards to contract brood-nest, and last, but not least, pure Italian bees in well-painted chaff hives, in the shade of trees.

Notwithstanding I have had uniform success in wintering bees in the house-apiary, I wish to class it among the things I do not recommend on the score of economy and convenience. I keep bees only in the south side, and it is more work to care for them than for an equal number in hives. You had better invest your money in chaff hives. I want no bee-bench, bee-shed, nor bee-house of any kind. I want no queen-excluding honey-boards, no sections larger nor smaller than one pound, no reversible frames. I fill my wired frames clear down to the bottom with foundation, and there is no necessity of reversing them to get them filled with comb; and if the honey in brood-combs is uncapped when the sections are put on, the bees will remove the honey as fast as the queen needs the room.



WELCOME APIARY
QUEENS REARED IN FULL COLONIES
Welcome Apiary
J·B·Hains.Prop'r.
Bedford, O.
C.Hoyt Sc.
MURRAY-HESS. CLEV. O.

APIARY BELONGING TO J. B. HAINS, BEDFORD, OHIO.

In addition to the apiary illustrated above, I have six others, in adjoining towns, aggregating about 200 colonies, and they are managed for comb honey principally, while my home apiary, which is kept as near a hundred as circumstances will permit, is devoted to queen-rearing and the production of extracted honey.

My winter loss in my home apiary is usually about ten per cent, composed largely of united nuclei. My report for the winter past is as follows:

Of 86 stocks on summer stands, lost 4; of 25 in house-apiary, lost none; of 18 in cellar, lost half.

I have purchased about as many bees as I have sold during the last sixteen years, in which time I have increased from 3 to 300 stocks. The largest yield of honey obtained from one stock in one season was 120 lbs. The average yield, year after year, has not exceeded one-fourth that amount. On the whole, I believe I have received just about a fair compensation for the money invested and the time devoted to bee culture, and am fairly satisfied with the result, as I expect to earn about a hundred cents to get a dollar out of any legitimate business.

Although this article is already too long, I wish to refer to one feature of the work in our apiary, and that is, it is largely done by women, which demonstrates that women can adapt themselves to the business, and become successful apiarists. Mrs. Hains and her cousin, Miss Bennett (who, by the way, are treasurer and secretary of the Progressive Bee-keepers' Association, which holds its next meeting in this place May 6th) have almost exclusive charge of the queen-nursery, as well as other departments of the work. Inexperienced persons would not hesitate to pronounce them wasteful in the extreme should they witness their selection, or, rather, rejection, of all small and medium sized queen cells—a rule which they rigidly enforce, believing that none but the most perfect are worthy to bear the title of royalty, and that, through careful selection, we may expect to come the nearest to realizing the hopes of all bee-keepers, which is, securing the best possible race of bees.

Bedford, Ohio, Apr. 1, 1886. J. B. HAINS.

Friend H., I am very glad indeed to hear that your apiary is managed by women. Perhaps this has something to do with the neat and tidy appearance it presents. I remember Mrs. Hains quite well; and, if I remember correctly, she does not look as if the duties had been so arduous or fatiguing as to wear her out, either mentally or physically. We should be very glad indeed to have some reports from either of the ladies. I fear we are not having so many communications of late from the other sex as we used to have in former volumes of GLEANINGS.

WINTERING BEES UNDER SNOW.

FRIEND MASON GIVES HIS EXPERIENCE IN THE MATTER, AWAY UP IN MAINE.

IN GLEANINGS of Apr. 1, J. H. Manning asks you if you have ever successfully tried the plan of letting bees be under the snow for two months or more. I have thought many times, while reading your advice on this matter, that I should like to know if you have ever thoroughly tried the plan of letting the bees be covered for three months with snow; and, if so, I have wondered why my bees fared so differently from others. I tried it for years, and made a loss every year, and every year I laid it to other causes, because I found it advised by what I regarded the best authority. My bees are so situated that they have good drainage, as you will see by looking at a picture of my apiary which I send you, with the exception of what few bees are in the sheds, which are shown in the picture. The bees are arranged on grades, one above another, running around a bank; those on the lower grade are all covered with snow first; those on the second grade are not covered so long, and those on the top grade are never covered at all, and always come out the best, and the second grade next, while the third grade always comes out damp, moldy, in a dying condition, or dead. Now, I have noticed this so many times that I am satisfied that covering with snow is an injury to my bees.

J. B. MASON.

Mechanic Falls, Maine, Apr. 5, 1886.

Thanks, friend M.; but I am a little surprised to receive these facts. Not only have I made it a practice all my life to leave all the snow just as it falls, but I have heard the same thing from so many other veteran bee-keepers that I supposed there was no doubt in the matter; and if snow does do harm, it is probably because you have it so much deeper than we do, and remaining on the ground so long a time. We seldom have the snow remain on the hives longer than a couple of weeks — sometimes, perhaps, a month; but very rarely so deep as to cover the hives as much as one week. Going around to the hives as fast as the snow falls is so much of a task that I think I should much prefer to set the hives up on high stands, or, better still, on high ground, situated as you suggest your upper row is.

OVERSTOCKING.

WHAT WE DO KNOW AND WHAT WE DON'T ABOUT IT.

I FANCY I hear the reader say, "You don't know any thing about overstocking;" to which I can retort, "Neither do you." I believe, however, it is a subject of very great importance, and, possibly, by talking about it, even if only to tell what we *don't* know, we may eventually learn something about it.

It is in the memory of many living bee-keepers, when it was very common for farmers and others to keep a few bees, so that, on a day's journey, many apiaries would be past, if from one to ten colonies could be called an apiary; but a collection of 100 or more was unknown. Now, however, one may make a day's journey and scarcely see a hive at any farmhouse by the way; but within a few years very many have made a specialty of the business, keeping fifty or more colonies in one place.

There are those who believe that, in the near future, bees will be principally kept by those who make bee culture a principal part of, if not all, their entire business. The tendency of the last few years has certainly been in that direction, and even now many a man is asking of himself, if not of others, "What is the outside limit, for greatest profit, of the number of colonies I can keep in my apiary?"

It is a very slippery subject. No matter how many facts we may gather, so great are the varying conditions that surround them that any positive, definite conclusion always evades our grasp. For instance, Bro. Doolittle (p. 13, GLEANINGS) gives some very interesting facts as to the product of his field; but as to his conclusions, there are a good many *ifs* in the way. He says that one year 500 colonies gave 15,000 lbs. surplus, and afterward 200 colonies gave 24,000 lbs. surplus; and from those and other data he deduces certain conclusions. Here are certain things that he *knows*, and he has the right to use them; but when he takes along with them something that he does *not* know, and uses it as fact, he vitiates his right to correctness of conclusion. The thing that he does *not* know, but takes for granted, is that the product of the field was the same each year. Just here is the great stumbling-block in the way of making any progress in the problem, just this variableness of seasons. He may say there was the same amount of bloom each year, but that doesn't settle it. Every observing bee-keeper knows that he can not tell by appearances the amount of nectar the bees can gather. One year I obtained over 16,000 lbs. of surplus; and another year, from about the same number of colonies, and with a better show of bloom, I got 2000 lbs. So we see how difficult it is to get at any thing tangible. Nevertheless, Bro. Doolittle's contribution is of value, and I presume he was as fully aware as any one of the difficulties of which I have been speaking. If we can get a great mass of facts bearing upon the matter, we may get some knowledge that may be of value.

I am not unaware that there are those who say there is no danger of overstocking, and even a few who insinuate, or say plainly, that there is no possibility of it. To these latter few, I want, in all kindness, to enter a most earnest protest against the utterance of any such sentiments. Please, brethren, consider the mischievous tendency of such talk. It may make no difference to you whether you are right or wrong. You have only a few colonies, and can be little affected by any view; but here is a man, limited in experience, who succeeds in getting a good crop, and reasons thus: "I may just as well have five times as many bees, and get five times the crop;" so, by increase and purchase, he starts the next season with a fivefold number, and, as a result, there are so many bees that the field barely gives them enough for their own support, and not a pound of surplus is obtained. If you say this is an exaggerated case, not likely to happen, let me give you what is likely to happen, and has happened.

Mr. Smith has an apiary upon which he depends for support. As nearly as he can decide, he has increased to the maximum number for greatest profit. Mr. Jones happens to live within half a mile or a mile of Mr. Smith, and, believing there is no such thing as overstocking, commences to build up an apiary. Every single colony Jones keeps is a damage to Smith; and if he increases to equal the number Smith had, Jones will himself make an ignoble failure. I have no desire to put a gag on any man's mouth to prevent his uttering his honest convictions; but I protest against any one of influence making a statement of a supposition as a fact, that he does not know to be a fact, when such statement may lead to damage and loss on the part of others. If any brother happens to have any clear conviction on the subject, with proofs to support it, by all means let such brother arise. There are a good many of us who will be glad to be convinced—our prejudices are all in that direction. I, for one, could afford to pay a man well to come and satisfy me that I can keep 300 colonies in one apiary, and realize as much profit from them as from a smaller number.

If I were asked to prove that 300 colonies in my apiary would be less profitable than a smaller number, I am not sure that I could do it, past all contradiction. I think, however, I could give some facts pointing in that direction. For instance, in 1880 I started with 200 colonies, spring count, in one apiary; took no honey to speak of (58 lbs.), and decreased to 162. Practically these bees secured honey enough for their own living, but no surplus. Am I not pretty safe in concluding that these bees got about all the field afforded? If I had had only 100 colonies, would they not have stored as surplus a large part or the whole of what the remaining 62 or 100 gathered for their own support? Another thing: There are a good many bee-keepers who have kept 250 or more colonies. Is there one of them who keeps 250 in one apiary? Does not each one show his belief in overstocking by the trouble and expense he incurs to establish out-apiaries?

We are still left to struggle with the question, How many colonies are required to overstock a given locality? or, rather, what is the number for greatest profit? What facts can we have bearing upon this? Bro. Doolittle has figured that 250 is the maximum number to be located within two miles of his house. This would allow a distance of four miles between the two most distant apiaries, and does not say how many might be kept in one apiary. About the most I can say very positively about my locality is, that in one particular year 200 colonies proved quite too many. What further light can we have?

THERMOMETERS.

The first thermometer you sent me was so long on the way it had time to get broken; though how it could be broken with such careful packing, I can not imagine. The second came very promptly, and is a nicer thermometer than I can buy here for the same price, and, so far as I can judge, just as good a thermometer as one which cost me 35 cents. Still, how do I know which is right and which is wrong? In the winter I keep four thermometers in constant use, and they vary about two degrees. Now, if I had one that I knew was right I could correct the others by it. Possibly, what I insist upon is impracticable and too expensive; but it is so desirable that I may be excused from further mention. If you, Bro. Root, can not buy accurately tested thermometers, get *one* in some way that you know to be correct. Then test others by it, and put in one lot those that prove entirely accurate. Perhaps another lot may be just one degree too low all through; but if the purchaser knows this he can make the proper allowance. Another lot may gradually change from being correct at 20° above to being too high or too low at some other point. Now, put price enough on these to pay for all trouble, and, if necessary to put on treble price, I don't think many of the correct ones would stay on your hands. We want some place where we can all buy thermometers, and *know* something about them.

C. C. MILLER, 340—324.

Marengo, Ill., Apr. 5, 1886.

Friend Miller, I think I can give you another fact in this matter of overstocking. With 300 or 400 colonies in our locality each summer, even though many of them are queenless, and consequently not full of populous colonies, our locality is all the while overstocked. No one can keep bees within a mile of us to any profit. They have tried it repeatedly, and I think they have all given it up. During great yields of honey they might do tolerably well for a little time; but in the end they decide it doesn't pay. For the same reason, honey-dew does us very little if any damage. There are so many mouths to feed that they use up the honey-dew, and almost every thing else, as fast as it comes.—In regard to thermometers, the manufacturers are now at work at a lot of standard tested thermometers, made especially for us. You may not be aware that the usual way to test thermometers is to try them at the freezing-point and at the boiling-point, then take it for granted that they will be right at other points. Now, although all show alike at these two extremes, they may vary considerably at other points. For instance, when it gets to be 20 below zero they won't tell quite the same story; and they may also vary some at ordinary summer temperatures, say 70 or 80 degrees. These new ones are to be tested at four different points—one down below zero, one at freezing, one at 60 or 70, and at the boiling-point. The price will be 35 cts. each. Besides the above tests, the scale will be longer so the degree-marks are more easily seen than the common ones. We have not yet decided whether they can be safely sent by mail.

FRIEND VANDERVORT'S HOUSE-APIARIES.

FRIEND WRIGHT TELLS US ABOUT THEM.

FRIEND ROOT: I have just received a card, asking me to tell you about friend Vandervort's house-apiaries. I will try to do so as best I can. From what you have said, I think that you have a very incorrect idea of friend V.'s house-apiaries. They are made very cheap. I don't think that they will cost to exceed one dollar per colony for the number of colonies to be kept in each house. The house is made in sections; the walls are double, and are packed with four inches of sawdust all around, under the bottom and over the top. The house can be taken down, loaded on trucks, and taken anywhere you wish to have it. First take off the top, then the sides and ends, and your house is ready to move.

Friend V. was moving one of his house-apiaries when I was there. For a house to hold 40 colonies, the house would have to be about 8 x 16 feet, and 7 or 8 feet high. There are two rows of hives on each side of the house—one on the floor, and one on a shelf about 3 feet high on each side. The house is nearly full. There is no place to store or extract honey. Above each hive there is a pigeon-hole, or air-hole, about six or eight inches square. These are opened and closed by a slide door; when it is cold, these are kept closed; and when it is hot, they are kept open. Friend V. tries to keep the temperature at a point where the bees can build comb, and evaporate and seal up honey at all times during the honey season, and at the same time keep it low enough not to excite the swarming fever. He said he had not lost a dozen swarms from these houses by absconding, in ten years. If a cold storm lowers the temperature, friend V. drives at once to his house apiaries and closes the little doors; when the temperature rises, he opens them again. He uses nine-frame hives; the frames are about the same depth as the Simplicity, but one inch longer. I believe he takes all of his honey in 2-lb. sections. He uses a case something like the Heddon, except that he uses separators, and has no partition between each row of sections. The sections rest on a tin made like an inverted T, thus: ⊥. The sections rest in the corners, and the separator rests on the knife-edge; one tier of sections is put in, then a separator, and then another tier of sections, and so on until the case is full; then a false side, or follower, with two steel springs, is put in. These springs press every thing tightly together. The case is placed on the hive so that the sections are right over the frames, and the space is often built full of brace-combs. These, friend V. carves off with a long knife. This would be distasteful to me, but he seems to enjoy it; and as long as he gets the honey, I suppose we have no right to complain.

You spoke in your foot-notes to Bro. Clarke's article, about bees getting on the floor. They do get on the floor, and die there—lots of them; but friend V. has got used to walking over dead bees, and doesn't notice them. I was there in April, and the bees in these houses were so strong that they were building bits of comb; and in some hives the bees were actually crowded out. No honey is ever taken out of the cases at the house-apiaries. The cases are taken to the honey-house at home, the honey removed, the cases refilled, taken to the house-apiaries, and put on the hives. If I remember correctly, friend V. told me that he preferred to work his bees in chaff hives out of doors; but this he can not do away from home, on account of thieves. They have tried to break into these houses; but when I was there they had not succeeded in getting through to the bees, although they had damaged the houses some. I stated that the houses were made in sections. I will say that it is not necessary to make them so, unless you wish to; and if I were building one for myself, I would build it solid, just like any other building.

If the above is not plain, and you don't understand it, I will answer any question you may ask.

GEO. A. WRIGHT.

Glenwood, Susq. Co., Pa., Mar. 12, 1886.

Many thanks, friend W., for the information you give us. You say no honey is ever taken out of the cases at the house-apiaries; but how does friend V. get the *bees* out? This point has been one of the great troubles in planning expeditious work in the house-apiary. I have suggested letting the cases of honey be until cold weather drives the bees down into the brood-chamber; but the honey gets badly soiled or darkened by so doing. I should think it would keep friend V. pretty busy, driving to these house-apiaries and moving these little slides, every time the weather changes. Can't he have an automatic regulator that would work them the same way that we see the dampers of some stoves operated by the contraction and expansion of a bar of metal? You see, I am first on this invention, do you not? We should be very glad to have friend V. himself tell us something about how he works, and the immense crops of honey he gets.

PROVERBS FOR BEE-KEEPERS.

BY REV. W. D. RALSTON.

THE ways of bee-keeping are not all ways of pleasantness, nor are all the paths thereof the paths of peace.

2. Man is to eat his bread in the sweat of his face, and there is no exception made in favor of the bee keeper.

3. To work successfully a man must work wisely. To work wisely with bees, one must know their nature and habits; these can be learned only by careful study and observation.

4. We live in progressive times, and the true bee-keeper must be progressive.

5. In bee-keeping, as in other things, the diligent are crowned with success.

6. The obstacles in the way of successful bee culture are, ignorance, carelessness, being too eager to increase the number of colonies, and *cold winters*.

7. A fair knowledge of bees, faithful attention to the apiary, and a thorough and timely preparation for the honey-flow, swarming, and wintering, will make any man or woman a successful bee-keeper.

8. A tyrannical Pharaoh demanded of his workers the full tale of bricks, but furnished them no straw. Do not demand from your little workers the full tale in pounds of honey, when there is none in the fields, or when you reside in a region poor in honey-yielding plants.

9. Carefully lay up your honey-crop where thieves (*especially robber bees*) can not break in and steal, and your empty combs where moth worms will not destroy them.

10. Profitable bee-keeping greatly depends upon a gathering-up of the fragments, that nothing be lost. Fragments of time can be used in caring for bees, fragments of lumber in making hives and frames, fragments of combs for wax; and every drop of honey is useful; even though mixed with dirt, it can be fed to needy colonies.

11. Some bee-keepers seek their profits in raising bees or queens to sell; but remember, that the true aim of bee-keeping is to supply our markets with delicious honey.

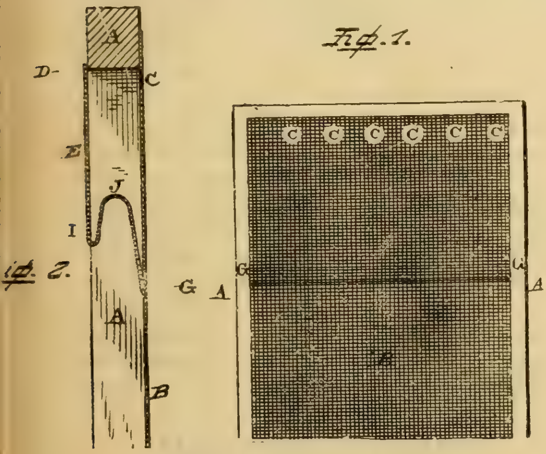
12. Live not for self. Make your knowledge profitable to others seeking to learn bee-keeping, that the coming generation of bee-keepers may excel the present, increasing in numbers and in knowledge, until every pound of honey secreted by the unnumbered flowers of our land is gathered.

Hopkinton, Iowa, March 8, 1886.

AN IMPROVEMENT ON SCREENS FOR KEEPING OUT FLIES.

ALSO SOMETHING FOR BEE-KEEPERS TO PUT ON THE WINDOWS OF THEIR HONEY-HOUSES.

WIRE cloth over the windows and doors is a grand thing, as everybody can testify who has tried keeping house with and without it. But suppose the flies all get on the window and stick there, what then? Over at our house the women-folks take a cloth and beat the poor insects to death, and then tumble them outdoors, maimed, sick, and wounded. It is hard, I know; but then, "flies have no business to be flies." We can not have our furniture all spotted and specked up, nor have our ears and noses tickled when we want to take a nap after sunrise on a June morning. Well, our enterprising friends of the Hub Manufacturing Co. have got out a little device that costs only 10 cts., which lets the flies outdoors just as fast as they want to get out, but it does not let them come back again.



WELLS' PATENT WINDOW-SCREEN.

Figure 1 shows the screen as it is seen from the outside. Figure 2 shows a sectional-end view. Perhaps I might remark here, that the engravings are not very good, and that they were not made by *our* engraver. The machine that is offered for sale for 10 cts. is shown by E, I, and J. It is a strip of wire cloth as wide as the window, and bent as shown above. At J some round holes are punched in the wire cloth, big enough to let a bee or a fly get through; then up at the top edge of the outside screen some more holes are punched at C. The flies buzz along up the screens until they get to J, when they crawl through the holes made on purpose, and, finding themselves "in a box," they hasten to get out at C. We have not yet had an opportunity of trying it with bees, but there is hardly a question but that it will work all right. We have them in stock, ready to ship, three different widths, 26, 28, and 30 inches. They can be sent by mail safely for another 10 cts. Printed instructions, for fastening them to window-screens go with them.

HONEY VERSUS SUGAR FEEDING.

SOME PITHY REMARKS FROM FRIEND SMITH.

FRIEND ROOT:—On page 97 of GLEANINGS, Mrs. Harrison, I think, gives us her honest convictions in regard to the honey and sugar question; and (allow me to consider that you are the president) I would heartily say "aye" to her article in *general*, and to her resolution in *particular*. But the expression, "Now let us feed our bees the dark, rich, good sweet honey, and not depress the market with it," I object to, and upon these grounds:

1. Because I can not winter bees successfully on late-gathered stores which are composed of this "rich, dark" honey.

2. I have no difficulty in selling, at good prices, all of my buckwheat and goldenrod honey. In fact, eight out of every ten of my customers prefer it to either clover or basswood honey, even at the same prices.

She also writes, "Now, it is advocated to take away the honey from the bees, and give them sugar syrup instead, benefiting the sugar market to the detriment of honey. Are we going to teach the bees that their own production is not fit food for them, thereby?" etc.

I should like to ask how the purchasing of sugar is to injure the honey market; that is, in the manner that Mrs. H. concludes it does. If you take 1000 lbs. of honey from your bees and replace it with sugar syrup, to be sure you help the sugar-trade; and if you sell this honey for home consumption, the way that all honey should be sold, why is it not a benefit to the public and to the honey-trade? I think we never shall see the day when honey is to take the place of sugar in the markets.

As to "teaching the bees that their own production is not fit food for them," how about "honey-dew"? Does not Mrs. H. advocate teaching the bees that our modern movable-comb hives are better adapted to their needs than the trees which nature provides? Why not the same, then, in regard to their food? When man finds that well-sealed sugar stores are better for the bees than poor honey, why should he hesitate to feed it?

I bought my granulated sugar at 7 cts. per lb. by the barrel, and, of course, it did not cost me much over 6 cts. per lb. when made into syrup. I did not sell a single pound of dark honey less than 9½ cts. per lb., and I did not peddle it either. Moreover, I had to buy several lots of my neighbors to supply my customers. Now, I claim that I received enough extra for my honey to defray the expense of feeding, besides having swarms in better shape to go into winter quarters.

In the article following Mrs. Harrison's, Mr. Wright says: "It is very embarrassing to me when I go to the city to sell honey, and begin to show my samples, to have the merchant look up, with significant grin, and ask me what I fed my bees." Now, I have had the same question asked me by merchants and consumers a score of times; but I can assure you that it did not embarrass me in the least. I always tell them that I make a *practice* of feeding *pure granulated-sugar syrup*, and that I will give them fifty dollars if they will prove that there is one ounce of said sugar in my *honey*. My sales of honey, and the prices that I received this season for the same, will bear me out in saying that the "feeding business" does not injure my honey-trade.

I believe, as does brother Root, that if we must feed sugar we should educate the public to it, and not conceal a single action in regard to it. Perhaps Mrs. H. and Mr. W. meant their remarks for their immediate localities; if so, then they will pardon my seemingly hasty criticisms.

In concluding this article, allow me to say, Bro. Root and others, that if you are "riding the sugar hobby," just stick to the saddle until you are *sure* that you are wrong, then dismount.

Pittsfield, Mass., March, 1886. CHAS. H. SMITH.

Below we give a communication from another friend, on the opposite side of this subject.

FEEDING SUGAR INSTEAD OF HONEY, WHEN HONEY CAN BE PURCHASED AT 40 CTS. PER GALLON.

A. Wright speaks, on page 98 of GLEANINGS, in regard to feeding our bees sugar syrup, and thus building up the sugar-manufactories at the expense of the poor apiarists of America, by using and advising the use of sugar in feeding our bees, instead of giving them their own natural production, honey, when they require to be fed. Is it possible that we can produce any article of food for bees that is superior to their own natural product, honey, to sustain life and bring them through winter in a better and more healthy condition? I should say, it is not possible. Is it a fact, that artificial food is better than their natural production, honey? If so, why? Certainly it is not so according to the law of nature, in any other one thing that I know of.

There are many points in friend Wright's letter that we as bee-keepers should earnestly consider; and it is necessary that we should do so in justice to ourselves and to one another. We are forming a "Protective Union" against such things of oppression as come through legal prosecution, and why not in this matter of feeding bees, by using honey instead of sugar, thereby opening an additional market for the disposal of *thousands* of *pounds* of honey where sugar is now fed, and thus very naturally assist one another? for where some of us have to feed, others of us have *honey for sale*, and for which we are trying to create a market for its disposal, instead of utilizing such an extensive opening for the disposal of it among ourselves as is given us by force of circumstances and nature, and which is being fast yielded up to the sugar-manufactories, while we seek other openings ahead.

I have already fed 250 lbs. of granulated sugar since January 1 to my bees, owing to their very weak state and small stores, caused by having run the most of them in the queen-rearing business quite late in the past season; still, they have not more than half enough stores to carry them through to spring; this sugar cost me 8 cts. per pound, and I used it, too, after having the offer of squeezed honey at 60 cts. per gallon (squeezed honey is that which has been squeezed from the combs by hand, balling it up and squeezing with the hands, the only method that is practiced here in the South where box and gum hives are *exclusivly* used). Why did I do this? you ask. Simply this: The sugar is here at hand, while the honey is 70 or 80 miles off; and rather than order it and wait, I used sugar. Now, since considering this matter, as I take it, in its proper light, I shall send and get the honey, and not use any more sugar to the exclusion of honey, thereby affording a sugar-market among *ourselves* to the exclusion of *our own* products. No, sir!

Now, friends, let me give you a few facts. There are quantities of honey sold in E. North Carolina —squeezed honey, at from 40 to 75 cts. per gallon. Last summer, several parties I know of went to Wilmington, N. C., to dispose of a barrel of honey each, and they were offered only 40 cts. per gallon for it, and but little sale for it at that. It is retailed by the gallon at the producer's door for 60 cts. per gallon. Now, what need to feed sugar, is there, since this honey can be bought and put at your door for less than sugar is *now* at its very *lowest cost*, while these prices, as given for honey here, do *not fluctuate*, as does the price of sugar? This state of things will bear serious consideration, and a change, if we desire to assist ourselves and one another too, and aid the bee-keepers in being successful apiarists. 4—ABBOTT L. SWINSON, 71—66.

Goldsboro, N. C., Feb. 5, 1886.

The opening article answers you in part; and another thing, friend S., a pound of granulated sugar makes more than a pound of syrup as thick as honey; and, again, I think I am correct in saying that it goes further, pound for pound. Sugar syrup is pure sugar. The honey gathered by the bees is not only grape sugar, a large part of it, but it contains gummy matter and a great variety of foreign substances. You have yourself also given one powerful argument in favor of sugar. It is always to be had at your nearest grocery or country store, at about its actual cost, while the honey is a good way off, as in your case. In your opening paragraph, you speak of the honey being the *natural* food of the bee. I don't believe it is worth while to quote nature very much. Nature's way would be to let our cows go without milking, and to let our hens go without gathering the eggs. We are assisting nature at every step—or, if you choose, improving on nature's process. Modern bee-keeping is almost all — *unnatural*.

REVERSIBLE SIMPLICITIES.

FRIEND SHUCK'S EXPERIENCE IN THE MATTER.

I WISH to add to the remarks of Hemphill & Goodman, in GLEANINGS for March 15, that I used substantially the same thing as much as eight years ago. I advertised the hive for *sale*, and applied for a patent on it more than a year ago. In order to make this form of hive as practicable as possible, I fill the trough in the metal frame-supports with strips of wood, thus converting them into the old-fashioned rabbet (metal rabbet, as generally used in this connection, is a misnomer; they are not rabbets any more than they are O. G. moldings), so that when propolized they will stand firmer than when on the thin edge of the metal supports. I then put strips across the top of the frames near each end of the hive, that are just as long as the hive is wide inside, and just thick enough to come flush with the top edge of the hive body. On top of this I clamp my invertible top-board, and the arrangement is perhaps as perfect for inversion as this form of frame can be made. I hope everybody will try this, if only to note the horrid deformity of the ordinary hanging frames when inverted. They look well enough when well made and properly spaced, if you view them only from the top; but to turn them over and take a peep at the other side is discouraging, to say the least. I always want to turn it back and try it over again.

As a complete invertible hive it has the disadvantage that it may be wrong side up when the frames need handling, and must be righted before you can take them out. The hive can also occupy but two positions—right side up and the reverse. A complete invertible hive possesses the most advantages which can occupy four positions, either of which can be given it in a moment, and without inconvenience to either the bees or their keeper.

J. M. SHUCK.

Des Moines, Iowa, March 20, 1886.

Friend S., you have hit it exactly, in saying that the appearance of a Simplicity hive, or any hanging-frame hive, is just awful when turned over and you take a view of the bottom-bars as they appear when turned uppermost; and I felt just as you did, that when I got it upside down I felt anxious to turn it back again right side up. We, however, put some cinders and sticks between the frames where they pressed together, and with a little pains made it look tolerably presentable.

TEMPERATURE OF BROOD-NEST.

WERE DOOLITTLE'S EXPERIMENTS ON PAGE 191, LAST YEAR, IN ASCERTAINING THE TEMPERATURE OF A COLONY IN WINTER, FAULTY?

ON page 43 we find, among others on the subject of "upper absorbents," the assertion that "moist air is heavier than dry, especially when cool." I wintered about 25 colonies on summer stands during the winter of 1883-'4 in my Climatic chaff hive. They stood close together in one row, facing east, with a tight board fence on the west, and stable on the north, with temporary board roof. I had tight-fitting division-boards on each side of the brood-nest, with a chaff box on top instead of cushions. That part of my hive which incloses the brood-nest (first story) is chaff packed, each end being four inches thick, the end walls and division-boards extending one inch above brood-frames. This gives my chaff box, or cushion, a drop of one inch to act in conjunction with chaff walls of hive in retaining heat.

My boxes used that winter were made of inch pine, bottom of burlap, and filled with about seven inches of wheat and oat chaff, and the box set down on the nine brood-frames; the box fit close (as you can make wood fit against wood) to the one-inch projection of end walls and division-boards, as above explained. The entrance I left open and kept free from snow; the cover, or cap, had a 1¼-inch hole covered with wire cloth in each end. Now comes the test of the scientific assertion, that "cool moist air is heavier than dry." In the spring, upon examining these hives I found the majority, if not *all*, as nearly as I remember, of the chaff boxes with an average of *2 inches of wet, moldy* chaff on *top*, and the rest of the chaff, four and five inches down to the bees, nice and dry; and in hives strong in bees, the chaff was warm toward the bottom. I had a clustering-space under the burlap bottom. I have discarded the boxes, and use, instead, cushions, pretty thick, with a Hill device sewed fast to the under side of cushion. The cushion and device can be stored away each spring together, without separation. I use the cushion instead of the box, for the reason that a cushion can be made to fit *snug* all around in the one-inch drop alluded to, where the wooden boxes would allow heat to escape.

Now, I believe, from my experience so far, that a cushion about 8 inches thick, or thicker, made to fit *close*, with a clustering chamber under it, and the entrance left open, will allow of a *slow* draft, insufficient to carry off enough heat to be detrimental to the bees, yet causing the excess of moisture to be carried and deposited partly on the *upper* surface of the chaff, and part escape through the holes in the cap.

About my first experience with bees was some eight years ago. I tried to winter a few in American hives, by covering them up so snug and *thick* on the frames, with pieces of carpet and cloths, that the moisture *failed* to escape, and two out of three, I believe I had then, I found so wet that combs and bees were in a kind of "mush," too dead to make "wax." I do not understand why any one can object to upper absorbents, if the cushion is arranged to retain the heat to fit down close, and put on early enough so the bees may wax it fast.

I examined a number of colonies this week, temperature about 10 above zero, and found, in every one at which I peeped hastily, the bees clustered in the chamber made for them under the cushion.

I was thinking, a few days since, that if we could make a chamber large enough to hold a good colony the shape of the shades found on our parlor hanging-lamps, which are dome shaped, with a large opening in the top, as in the shade, and cover the whole with a *thick* chaff cushion, and let the moisture escape through the opening into the chaff cushion, it would insure almost to a certainty their wintering, as the bees could be *all* in *one* cluster, and the heat thus generated would defy our severest winters.

We can not winter bees successfully where the cluster is separated by one or more combs of honey, as must be the case where wintered in the brood-nest; not enough bees can cluster between two combs to stand our severe winters. If the above "shade" chamber were made out of some light material, like the wooden butter-plates found in our groceries, and thickly perforated with about ½-inch holes, then pour around it about 20 lbs. of "Good" candy, leaving the center open as in the shade, for the moisture to escape into the cushion, which would *completely* cover the chamber, sugar and all, it would, I believe, be an excellent house to winter in; the walls of said house would be "around and about them," and the bees could "just sit around" and lick the sugar when and where they might choose.

THE NORMAL TEMPERATURE OF A COLONY IN WINTER QUARTERS.

On page 191, in your foot-notes you say that disturbing the bees would cause the temperature to rise rapidly, and that you do not quite see that Mr. Doolittle had settled it; also, on page 91 our hibernating friend Clarke says, "Mr. Doolittle's experiments prove the extreme difficulty, if not utter impossibility, of ascertaining the normal temperature of the interior of a bee-cluster; for the moment the bees are disturbed and excited, the heat begins to increase." Now, I think you and Mr. Clarke a little premature in your decisions, as well as Mr. Doolittle's conclusion, the first day he drew the thermometer out from that cluster; for, notice, he left it in from 4 P. M. until the next morning; and in taking it out the act was so quick that the temperature did not rise from the disturbance caused at the moment of opening; the heat could not rise and affect the thermometer in the short time it would take him to reach in and pull it out. The bees surely had settled into their natural quiet state during the interval between 4 P. M. and the following morning.

In the second experiment, when five days intervened, in which the cluster would surely assume its wonted quietness (and Mr. Doolittle would not tarry when pulling out the thermometer, but he no doubt reached in and lifted it out *immediately*, and cast his eye as soon as possible on the instrument, before a moment's time could lower the temperature), would the bees have time, I should like to know, in the moment of time consumed, to affect the thermometer? I can not see it. Then, again, his thermometer gave the *coldest* point reached in the cluster during the five days, which was 63°. They were not disturbed while registering the above 63°. Why not, for that size of colony, in *his* make of hive, put the normal temperature at 63°? How can it be otherwise, when they had five days to cluster around the graduated part of the thermometer (which Mr. Doolittle inserted), and register *undisturbed?* The 63°, I claim, was the normal temperature of the cluster; for after the bees cooled down after inserting the thermometer, the cluster entered into a normal state, and the temperature would naturally be the lowest—i. e., 63°, during the cluster's five days of quiet.

About four years ago I spread my brood-nest in the center, giving about 1½ or 2 inches space between the two central combs for clustering. One day, when ½ degree above zero outside, I inserted a thermometer quickly in the space above mentioned—not among the bees, as the cluster was at one end of the hive, and I hung the thermometer at the other, where a few scattering bees were, taking it out when but a little time had expired (a few hours). The temperature had raised to 80° (summer heat). The hive was my Climatic, as described further back.

Two days ago, in same make of hive, I placed the thermometer (which hung outside, and registered 2° below zero) under the cushion, in the clustering-space under the Hill device, allowing the lower end of the thermometer to just touch the cluster and extend "out in the cold." I left it in only about 15 minutes, and it registered 40°. Two hives treated this way registered the same. In the first experiment I think I took the thermometer out too soon; the rise in temperature was caused, no doubt, by what little I disturbed the bees. The second I did not give enough time for the thermometer to register even the abnormal heat.

I am only an A B C, and have doubtless been presumptuous in the foregoing; but I wish some veteran would presume to prove me mistaken. School is open at all hours, and we are willing to learn. We little ones will throw stones now and then, but we will take the consequences, and probably learn something. WM. M. YOUNG.

Nevada, Ohio, Feb., 1886.

Friend Y., I can not see that your experiment particularly touches the question of the weight of damp air or dry air. The moist air ascended and dampened the chaff in your hives, because the air was cold outside and warmer inside, which always produces an ascending current. In regard to the temperature of the brood-nest, see the following article.

WINTER TEMPERATURE OF BEES.

FURTHER EXPERIMENTS IN THE SAME DIRECTION.

IN Mr. Clarke's article, p. 91, in reply to Mr. Doolittle, he endeavors to substantiate his hibernation theory. It seems presumptuous for me to cope with such able writers as Mr. Clarke and Doolittle; but, according to my observations, they are both somewhat in error in some of their conclusions; and I think that, by the time I am through, I can unsettle Mr. Clarke's hibernation theory considerably.

I infer, from Mr. Doolittle's article, that his experiments were conducted in the latter part of January and the first part of February; and he also had the benefit of colder weather than I did. But according to my experiments, a fall in the outside temperature does not always produce a corresponding lower temperature in a cluster of bees that is undisturbed, but, rather, the contrary, especially when taken at different times on the same day, as the following tables will show.

I am inclined to think that Mr. Doolittle's figures are too low, though different localities and different circumstances *may* cause a difference in temperature. If 15° of change in outside temperature, as Mr. Doolittle says, make one degree in the cluster, an outside temperature of 75° would give only 69° in cluster, which I think much too low. Is it not possible, Mr. D., if your thermometer is as long as the average one, that, when it was suspended between the frames, the bulb was situated almost at the lower extremity of the cluster? A common thermometer is about 7 inches long; and, if suspended the entire length below the cushions, would extend within two inches of the bottom of the frames; and as the temperature certainly decreases from the center of the cluster to the outside, is it not probable that your figures are too low?

The following series of experiments were all taken from one hive, though *partially* verified by experiments with other hives. The hive selected was one of my best hives, with the usual chaff cushion, and situated in a row of hives which stand about 8 inches apart. The spaces between, and about 6 inches at the back, are packed with straw, and over all is a temporary roof. I used a common thermometer by slipping the graduated scale, with the tube, out of the case. I then cut a slit in the mats (two of which were used, as one was gnawed full of holes), just large enough to admit the thermometer and hold it in its place when slipped up or down. It was then placed in the slit (without disturbing the frames), with the upper end extending about 3 inches above the frames, over which an inverted tumbler was placed, and the cushion over all. By raising the tube ½ to 1 in., the temperature could be seen at any time, and disturb the bees but little. The observations were taken about sunrise, unless otherwise designated; at noon, when it was possible for me to be at home at noon; and at night. I placed the thermometer in the cluster Feb. 9, and have the following results:

Feb. 10	Clear	Outside temp.,	33°	Inside temp.,	53°
" 11	"	"	40	"	62
" 12	Rainy	"	50	"	66
" 13	Damp	"	38	"	58
" 14	Clear	"	39	"	57
" 15	Showery	"	37	"	58
" 16	Clear.	"	22	"	47
" 17	"	"	16	"	39

At this point the hibernation theory had taken pretty firm hold on me, and I had begun to believe that the temperature of the bees *did* sometimes fall below the freezing-point. But, still having doubts, I investigated, and found that the bees had changed their positions, on account of the foreign substance in their midst, and left the thermometer fully two inches from the cluster, where it had doubtless been during the whole time. When it was again placed in the cluster, with the temperature outside at 16° above zero, it arose almost immediately to 80°; and, before closing the hive, it registered 96°! This knocked the hibernation theory out of me so completely, that it has never returned. The above table shows that the temperature outside the cluster averages about 25° above that of the outside air. The bees behaved themselves tolerably well after this, with the temperature ranging as follows:

Date.	Weather.	Time of day.	Out-side air.	In clus-ter.
Feb. 18	Clear.		27°	78°
" 18	"	Noon.	50	74
" 18	"	Even'g.	50	76
" 19	Cloudy.		40	72
" 20	Windy		15	76
" 20	"	Noon.	22	69
" 20	"	Even'g.	24	79
" 21	Cloudy.		26	65*
" 21	"	Noon.	36	64
" 21	"	Even'g.	38	74
" 24	Clear.		24	74
" 25	Rainy.		44	80
" 25		Noon.	53	75
" 25		Even'g.	40	75
" 26			15	79
" 26		Noon.	23	73
" 26		Even'g.	28	76
" 27			14	72*
" 28			18	72*

* Near outside of cluster.

Owing to the varying position of the center of the cluster, some observations are a little irregular; but I think those taken on the 18th, 25th, and 26th, are very nearly correct. You will notice one thing peculiar; that is, that the temperature is highest in early morning, lowest at noon, and intermediate at evening. This seems contrary to the natural order of things; but all my experiments in *cold* weather tend to confirm the above results. For some time I was at a loss to explain this singularity; but I have arrived at the following conclusions:

The colder the weather gets, the more closely the bees will pack themselves, and the harder will the outer bees crowd for a warm corner, making, on a cold morning, a knot of bees so dense as to be impervious to cold, and which retains nearly all the animal heat generated, thereby maintaining a high degree of temperature. As the day advances, and it grows lighter and warmer, the cluster relaxes and unfolds itself more or less, to make motion possible inside the cluster, in order to obtain their daily rations (and I think they are in almost daily need of food), so that they may be able to withstand the cold of another night. This, of course, would produce a lower temperature.

Then, if bees hibernate at all, they must do so at high temperatures; that is, the higher the temperature of the cluster, the more complete is the hibernation. I forgot to say, that the colony was examined about a week after the conclusion of the experiments, to ascertain whether or not it contained brood, and I found only a patch of eggs, about the size of a dollar.

THE CHAFF HIVE.

In friend Bish's communication, page 128, 1886, he says that I proposed to change the inside dimensions of the chaff hive; but, if he will refer back to my article (page 12), he will find it to the contrary. But, friend Root, *why not* change the dimensions, making the hive ¼ inch longer from back to front, in upper story, thus making it possible, with the ample space at the sides, to use a Simplicity body in the upper story? I think such a change would be received with great favor by bee-keepers in general. It will not interfere with the usual management of the hive, as the tin rabbets may still be put in their places, and the wide frames may at any time be used in the usual way. I think, then, that the chaff and Simplicity hives will make a perfect system of hives, as the different parts of each will be still more interchangeable. As you know, it is a great advantage, when a swarm issues from a hive, leaving incomplete sections, to be able to place the story bodily on another hive; but if you wish to change to a chaff hive, you have to pull the frames all apart and handle them separately.

I have about concluded to change the inside dimensions ¼ inch in the hives I make in the future—at any rate, for my own use. This increase in length will necessitate no increase in the length of the siding, but only a few minor changes, which will cause no trouble or extra expense on the part of the manufacturer.

E. E. CROSS.

Racine, Meigs Co., Ohio, March, 1886.

Friend C., your experiments seem to be quite conclusive, and are doubtless right.—I do not know of any reason why the chaff hive should not be made so a Simplicity may be set down inside of it. We used them this way some years ago, but it seemed to be so difficult to set the Simplicities in and set them out again that we abandoned the plan, and the chaff hive was contracted in the way we make it now, because there seemed to be no object in making it large enough to admit a Simplicity.—And now, friends, as winter is gone and summer is near, shall we not drop the subject of wintering, temperature, etc., for the time being?

WHERE DOCTORS DISAGREE, WHO SHALL DECIDE?

DOES THE ADDITION OF MOISTURE TO A GIVEN VOLUME OF AIR INCREASE OR DECREASE ITS SPECIFIC GRAVITY PER CUBIC FOOT?

IN the *Scientific American* for March 13, a querist, whose initials are "J. A. G.," asks as follows:

> 1. Is it true, that moist air is lighter than dry air at all temperatures?
>
> 2. Is not moist air that is cooled to the dew-point heavier than unsaturated air at the same temperature?

The *Scientific American* replies to the first question:

> Moist air is always heavier than dry air at the same temperature.

And to the latter,

> Yes.

Now, then, Guyot's Physical Geography contains the following paragraph in regard to the distribution of vapor in the atmosphere;

Water, whether in the sea or on land, is slowly transformed into invisible vapor, which, being much lighter than air—as 3: 5—rises, and is diffused through every part of the atmosphere. Thus the latter becomes the great reservoir of aqueous vapors.

My opinion is, that the *Scientific American* has made a mistake, or that they haven't got hold of the question asked by J. A. G. And, by the way, is it not our bee-friend J. A. Green who propounds these inquiries? If invisible vapor is lighter than air, to the extent of the proportion of 3 to 5, no wonder it rises and forms clouds. It may be said, the vapor rises and not the air, but I think this can not be true.

BUILDING UP A BEE-RANCH.

HOW IT WAS DONE IN CALIFORNIA.

IN November, 1883, I was teaching school near the central part of Ventura Co., in Southern California. Three seasons before, I had purchased an apiary which I ran for two years, and then sold out. Some of my neighbors, knowing I was interested in bees, offered several colonies to me at my own price. I paid from $1.00 to $1.10 apiece for fourteen colonies, returning the hives. I afterward purchased six more, paying 100 lbs. of honey for each colony when the original colony would make it. These last were bought after it was certain the season would be very good. I took out over 300 lbs. per colony, and increased my bees to 120 colonies in the spring of 1884. This honey, most of which was very fine, I sold at 4, 4½, and 5 cents per lb., net. Before the honey season was over I was obliged to move my bees out of the valley, on account of the fruit, the danger to teams, etc. The weather was so warm, and the roads so rough, that I lost 10 colonies in moving them about 20 miles.

The next year I took out about 40 lbs. to the colony and increased only 17 colonies. This was a poor yield. But very few bee-keepers made any honey last year. This year every thing looks as favorable as in 1884. My expenses so far have been for hives, which cost me about $1.50 each; a honey-tank, holding 3 tons, cost me $25.00; an extractor, $25.00; a honey-house, 16×16, two stories, $160, and honey-knives, smokers, wheelbarrows, heaters, foundation-machine, etc., about $50 more; so at the end of this season I shall have, probably, 200 colonies and $600 invested in the apiary and fixtures. With six years' experience, I can say that this investment will yield me on an average about $600 a year above expenses (not reckoning my own labor). I do not believe it will be profitable to keep more than 200 colonies upon my range, though there are places where they keep three or four times as many, and average ten or twelve tons of honey a year.

In 1883 I looked around for a place where I could both keep bees and raise fruit. After many days' hunting in the mountains I found a cañon a mile or more long, about 1500 feet above the ocean, and 15 miles inland. There are about 120 acres of plow-land in the cañon, or little valley. The soil is very rich, and the surrounding hills are covered with alfileria, mustard, sage, clover, and other flowers. The feed is very fine for stock, but there is neither wood nor water on the place.

I rented the place to a new comer, agreeing to build him a cabin and give him all he could make upon the place for plowing the land and taking care of my young trees. I put out 14 acres of fruit-trees, at a cost of about $30.00 per acre, planting apples, peaches, plums, prunes, apricots, pears, almonds, and nectarines. Trees mature so quickly here that mine, planted in March, 1884, produced some fruit last year, and this year are so full of blooms that I expect several tons of fruit. The value of what an orchard will yield each year in California is estimated at from $100 to $2000, the smaller number being usually much nearer the truth. The profits from orchards are often given, as with bees, by taking one tree (one colony) and calculating what 100 to the acre would yield in like proportion.

1885 was a dry year. To the first 160 acres I took up as a timber-culture claim, I then added 160 acres more as a homestead. The one who had rented my place the year before took it again on similar terms, giving me what I wished for my own use from the crop. He had cultivated about 50 acres of beans, corn, etc., making 1000 lbs. of beans to the acre (worth 3 cents per lb.), 20 centals of corn, etc. In 1885 the crop was much poorer, mainly because of a lack of proper tillage. This year I farm my own place, and the prospects are very bright for a large yield. What do you think east, of 60 bushels of corn to the acre, raised without one drop of rain from the time it is planted until after it is ripe? In my garden are two-year old tomato-vines, still blooming and bearing as they have for every month in the year. CHARLES M. DRAKE.

Springville, Ventura Co., Cal.

SURPLUS HONEY IN BOXES.

SOME NEW THOUGHTS FROM FRIEND DOOLITTLE, IN REGARD TO STARTING THE BEES IN SECTIONS.

ON page 181 of GLEANINGS, present volume, I find these words: "The most difficult problem I find in bee-keeping is how to make bees store surplus honey in boxes." As this was once the perplexing problem with me also, I thought perhaps by telling how I had solved it so I have no more trouble along that line, I might benefit some of my fellow-apiarists.

At first I tried the plan, so often given, of taking boxes from such colonies as had commenced work in them, and placing said boxes, bees and all, on the colonies which still refused to work, and in this way I was generally successful; but occasionally a colony would not yield to such persuasion. After trying various plans on these obstinate ones, I at last hit upon a plan which always brought any colony to terms. It was this: I went to a colony which had a surplus of drone-brood, and cut out a piece of said brood, fitting it in a single box or section, putting this section in the center of all those on the hive. Immediately the bees would enter this section to protect this brood, which resulted in a start being made in the sections all about it. The great objection to this plan is the trouble, and the getting of an inferior grade of honey where this brood was. As I did not like these two objections, I fell to studying, the result of which was that the next year found me reducing the size of my hives by means of dummies, or division-boards, so that the brood should be close to the sections, as was the case when the drone-brood was used. Upon looking over all these obstinate colonies I found that all of them were such as had much empty comb-space in the brood-chamber at the time the honey-harvest commenced, which space the bees filled with honey, when they began crowding the queen, rather than taking to the sections.

I have often noticed, that, if the bees start to storing in the brood-chamber to any great extent before entering the sections, such colonies will generally be unprofitable as far as section honey is concerned. For this reason I take away all combs, not occupied with brood, from the colony I am to put sections upon. Dummies, or division-boards, are used to take the place of the broodless combs taken away; and thus when the bees get a surplus of honey it must go into the sections, as they have nowhere else to put it.

Another thing, when I put on sections I put on only a few to start with, for a large amount of room given at the commencement of the season tends to discourage the bees. I generally give room to the capacity of from 15 to 20 lbs. to start with, and in a week add room for 10 to 15 lbs. more, and so on till the full capacity of the hive is reached. In this way the bees are led along so as to accomplish the best results. When hiving new swarms, they are allowed only from 4 to 7 brood-frames, according to the size of the swarm, which plan always gets them in the sections at once. They are allowed no more room below until 25 days after hiving, at which time their numbers are largely augmented by the rapidly hatching brood. At this time the hive is filled out (9 Gallup frames), and, if needed, more surplus room is added, so as to prevent what are called "virgin swarms" issuing. As soon as all the brood is hatched out of the combs in the parent colony, and the young queen gets to laying, this brood-chamber also is contracted to from 5 to 7 combs, and thus all are at work in the sections during the best of the honey-flow, to the best possible advantage. When the white-honey harvest is over, the sections are taken off and all hives filled out with combs to their full capacity, so that, as a rule, I have plenty of honey and plenty of bees for winter.

In the above, Wm. G. Norton (page 170) will find an answer to his queries. I will further state, for his benefit, that I use "duck" and enameled cloth on my hives in place of a honey-board, and these quilts are rolled back as more sections are put on, so that the top of the hive is kept covered. In this way I can put on few or many sections, as I desire.

Borodino, N. Y., Mar., 1886. G. M. DOOLITTLE.

Friend D., I congratulate you on having brought out a very valuable point indeed. Since you call attention to it, it seems very plain and clear, and I have no doubt you are right, although the whole thing is to me a new thought. I have often noticed that bees prefer to commence building comb as near to the brood-nest as they can get it—often building fins at the ends of the frames, rather than go a little higher up and work in section boxes. I have also noticed that they commence building new comb much quicker after the brood-apartment is closed up so as to make the bees fill it pretty closely. When they begin to feel the need of more room, and begin to crowd out somewhere, if we can make them crowd up into the sections it is just what we are after. The idea comes very seasonably; and let our friends all look to the matter of preventing honey-storing in any empty space in the brood-chamber as much as possible when honey begins to come in. I am sure, also, that it is much better to give more room to a colony gradually. A whole upper story at once is, as a rule, too much. Some may object to the time and extra manipulation, but I do not see how the best results can be secured without some pains and some work.

DO BEES HEAR?

AND DO THEY HAVE ANY VISIBLE ORGANS FOR THIS PURPOSE? AN EPISODE OF A SPIDER.

L. N. TONGUE, of Hillsborough, Wis., asks me the following question: "Do bees hear? Let Ernest examine and report. It is disputed by some, but I claim they can." Mrs. Chaddock, a short time ago, asked the same question, and I will now proceed to answer it as well as I can. I do not think we shall ever be able to render a decision that will be final to all parties. This question has remained in uncertainty for centuries. As long ago as 750 B. C., Isaiah seemed to believe that the bee possesses the power of hearing (Isa. 7: 18). Aristotle, who lived in the year 380 B. C., something over a hundred years after the time of Esther, of whom we have been studying lately, said, "*Incertum est an audiant*"—it is uncertain whether they (the bees) hear. Huber, to whom we are indebted for so many valuable observations, expresses his doubt as to whether the bee hears, and yet is inclined to think that they have something analogous to the power of hearing. Our own Prof. Cook, if I am correct, though I may be mistaken in the person, says that bees probably can hear, though there are no distinct visible organs which can be found, answering this purpose. Naturalists are not agreed as to the exact location of the bee's ear; but the majority are of the opinion that the power of hearing resides in the antennæ, or "feelers," as they are commonly termed, basing their arguments from the number and the analogous location of these organs. Others ascribe to the antennæ only the power of delicate touch, and not a compound organ of both hearing and feeling. They further assert, that bees are sensible to sound only as vibrations affect the organs of touch. It seems to me, in the light of present facts, that this position can hardly be tenable.

Let us glance for a moment at a few facts and observations. We are all familiar with the peculiar piping "zeep, zeep," emitted by the queen on certain occasions, as at introducing and at swarming time. Why does she do this? Certainly not for her own individual pleasure, nor that we, as human beings, may listen to her tiny voice. We must agree that this is manifestly a signal to the workers, and that the workers understand it. Many a time, in introducing queens, I have heard this sharp note. The workers would then show considerable signs of excitement. It is true, that scent may have produced this effect, but I think not in such a marked degree.

Once, while standing in front of a hive, I heard this peculiar piping of the queen. It was sharp and prolonged, and I then began to suspect something. Before I had time to form any opinion, out poured the bees from this hive by the hundred, until the air was filled with a large swarm. I naturally concluded then, and still think, that the queen gave her signal for the swarm to issue, and that the bees heard it. The queen may not always signal the time for swarming, but I feel confident that she did in this particular instance.

Again, the very existence of this piping note of the queen proves, to my mind, that it was not created without a purpose, and this purpose manifestly was that the bees should hear it and act accordingly, as they choose.

During my experiments recently in determining how long a few bees would live, caged on Good candy, I learned one or two other things besides. Some of the cages that I had for this purpose contained a single bee, and others a dozen or more. The cages were scattered through the various sections of a paper-holder, perhaps two or three cages in a section; and were so arranged that the occupants of one cage could not see those of another. On several occasions I noticed that, when the bees of one cage set up a buzzing, the rest all began, until it seemed like a whole swarm. Now, I think the bees of one cage must have heard those of another, in order for all to buzz at the same time as they did, for all other means of communication were cut off.

DO SPIDERS HEAR AND APPRECIATE MUSIC?

Whether the bee hears the drumming of tin pans, or can appreciate the delicate sounds of music, might be a matter of doubt—at least, I never heard of a bee that was spellbound at the sound of music. It is said that Sir John Lubbock, after playing the violin before his bees, was not able to induce them to waltz, beat time, or try the key of "one sharp" on him. Whether Sir John ever tried any thing of this kind, I am not prepared to say; at any rate, an indifferent behavior on the part of the bees is not to be wondered at. In books of natural history we read that spiders, however, seem to exhibit signs of keen enjoyment at the sound of the guitar or other instruments. When I first saw this statement it was too much for me to believe; but chancing, one evening, to play my accordion some years ago in the factory, one of my friends who was with me ejaculated all at once, "Oh, look at that monstrous spider!" As I continued to play, the insect advanced toward me, for reasons that I did not then suspect, and, before I was aware, it was perched upon my knee, whereon rested my accordion. Feeling a cold chill creep down my back as I discovered this intimate friendship, I shook the ugly "baste" upon the floor, stamping my feet as I did so. The spider made good his retreat, and disappeared under a pile of boards. When quiet prevailed, and I had resumed my playing, lo and behold! our good friend crept cautiously out as before. I will not say that he waltzed, but he *did* act as though he were spellbound. I then recollected what I had read, and naturally concluded that it was the music that delighted his worship. If I ceased playing, the spider soon crept away; and whenever I resumed he would reappear. I made repeated trials, with the same results, and on separate evenings too. On one or two occasions I called him out in this way to show him to my friends, who were a little incredulous.

It seems hardly possible that the vibrations caused by the music produced an agreeable sensation upon the antennæ of the spider, and that it was only a delicate sense of touch, and not of hearing. On the contrary it is reasonable for me to suppose that the spider not only *heard*, but enjoyed, the music. Whether a bee can appreciate musical sounds or not, we can not decide; but if a spider can *enjoy* them, I believe a bee can *hear* at least the "zeep, zeep," of the queen.

E. R. Root.

I will add to what Ernest has said about the calling of a queen, that I have repeatedly seen bees start, as if with one accord, toward a strange queen when she uttered this strange "zeep, zeep;" and, more than that, I have seen the bees on a neighboring frame start *en masse* toward the point from which the sounds proceeded, when a strange queen uttered this call; and, if I am not mistaken, I have seen them do it when the frame containing the queen was in one hand, and the bees that started in response to the call were held on a frame in the other hand. I am satisfied that bees can hear the call of their queen, or of a strange queen; but I am also well aware that a pistol may be fired within a few feet of them without our perceiving even a flutter or vibration of the wings.

HOW TO TAKE OUT SECTIONS.

THOSE 4000 BASSWOOD-TREES MENTIONED IN THE A B C.

CAN you tell me some good way to take the first row of sections out of your crate? It is easy enough after that.—I doubt not that many others would be glad to know the result this year of the 4000 basswood-trees mentioned on page 30 of A B C.—When I return combs to second story of the hive after extracting last time, the bees usually clean them up by gathering the honey into a few cells in the center of each comb, making it necessary to pass all combs through the extractor again. How can I get them to take this honey below, or will it be all right to leave it in the combs?

Salem, Columbiana Co., Ohio. M. F. Taber.

Friend T., the easiest way to take the sections out, if the case is all full, is to turn the case over, and, with a suitable follower, press them out all at once—the case being raised half an inch from the top of the table, with suitable strips of wood in each end. If you want to remove the filled ones, and leave the others to be finished, we usually have but little trouble in getting the first one out by means of a screw-driver or a heavy-bladed knife.—During 1885 our basswood-orchard yielded a tolerable crop of blossoms, and quite an army of bees could be seen going in the direction of the trees every morning while they were in full bloom. As there are some heavy forests of basswood near by, however, it is likely that quite a large part of the bees visited these forests.—The only way to get every drop of honey out of your combs after extracting, is to leave on the upper stories until the bees collect these little patches of honey and carry them down, toward the approach of winter. If some honey is left in the combs over winter it does no harm, providing your combs are wintered in some place secure from moth or robber-bees; that is, you do not want robbers to work at them when they commence to work in the spring or late in the fall.

WHAT TO DO, AND HOW TO BE HAPPY WHILE DOING IT.

Continued from March 15.

CHAPTER XIII.

Better is little, with the fear of the Lord, than great treasure and trouble therewith.—PROV. 15: 16.

As I commence this chapter during this 6th day of April, 1886, our country is beset with troubles on account of strikes because of the conflict between labor and capital. A great many are also in trouble because of the very low prices obtained for every thing, and therefore many are out of work. I bought a load of large beautiful "Northern Spy" apples at only 30 cts. a bushel. The man took that, rather than drive around from house to house, meeting only with the discouraged statement that they had more than they wanted already. At the very time I bought those apples, my own were rotting at the rate of a bushel a day, and I did not need any more. Another farmer sold me twelve dozen eggs for only an even dollar; and if one were to keep his poultry shut up, and feed them till they lay twelve dozen eggs, I am sure the feed would cost more than a dollar. Fifty bushels of turnips are shooting up sprouts out where they are buried, but no one wants them, even at 35 cts. a bushel, although they usually bring a dollar a bushel in the spring. A year ago last fall I thought I should like to try my hand at raising a piece of wheat. I was going to show the farmers what big farming and modern implements, underdraining, phosphate, etc., would do. How do you suppose it turned out? I think I got about 24 bushels of wheat to the acre; but I was offered so little for it I concluded to keep it to feed to my Light Brahmas. It is true, we have had eggs almost all through the winter, and I have enjoyed keeping the poultry; but I doubt whether the eggs would have sold for enough to pay for the wheat, and I doubt again whether the wheat would have sold for enough to pay for the expense of raising the crop, to say nothing about the value of the land, that cost me over $200 an acre.

Although labor is plentiful, and people are everywhere begging for a job, yet real faithful farm hands are not plentiful. Out of the hundreds who apply to me for something to do, I doubt if there is one who would feel greatly *worried* or *troubled* if he knew the crops he raised for me would not sell for enough to pay the wages he receives. He would doubtless think that was *my* part of the business, and that *his* was to do as he was bidden. May be he would think I had lots of money, and that I was doing it for fun any way, and that he might just as well have some of my money as anybody else.

Now, I presume I could write several chapters full of discouragements like the above. Shall I go on? I think there is no need of it; in fact, I think the better way will be for us to examine the above, and see where the trouble is. If this book is to tell you all what to do, and how to be happy in doing it, we can not very well have it filled with such doleful tales as I have just given you. I have before told you that the book was written for poor people, or any kind of people who have leisure hours, and want to know how they can make some money during those leisure hours. If somebody had asked me to write a book stating how people who are busy from daylight till dark could make *more* money by hiring other people, I think I should have said at once I didn't know how to write any such book. In fact, I very much doubt whether a book could be written to tell people how to make money by hiring somebody else to take care of their poultry, their garden, their greenhouse, or any of these things. All these kinds of industries need yourself, my dear friend. God wants you, and no substitute; and the first thing to do in any kind of business is to learn to be faithful and successful yourself, and in due time this faculty of being able to employ others will come. It can not be learned out of a book, although a book may be a great help to you; and this book, I feel sure, will show you the way in which you can be comfortable and happy, providing you are willing to work. In fact, I begin to think more happiness is to be found with small possessions, than where property has been left you. Giving a young man a good farm does not necessarily make him happy; and if he should get two or three farms by the death of relatives, it seems to me that, in the generality of cases, they would be pretty sure to make him unhappy. Our text says, "Better is a little, with the fear of the Lord, than great treasure and trouble therewith."

Now, then, about the low prices. There is a bright side to it, even, as there is to almost every thing else, if you take it in a bright and hopeful spirit. If apples are cheap, think of the number of juveniles that rejoice over healthful fruit in the spring of the year. At the time I was telling you how low apples were, I did not say any thing about the price of potatoes, although I thought of it. Potatoes bring readily 20 cts. a *peck* at retail, and the price will very soon be 25 cts., or a dollar a bushel, probably, for there are no potatoes in our town, of any account. I need not tell you that, at these prices, potato-raising is a very profitable business. It is true, that eggs are only 8 cts; but at the same time, butter is from 20 to 25 cts.; and I have just been informed there is no butter in our town. Do you see the point? You are to make it your business to fill up these gaps or vacancies. If your crops are nicely cared for, and nicely husbanded for safe keeping, and a scarcity occurs, you will get good prices; and even these same apples that have been begging customers at 30 cts. a bushel may bring a dollar in a few weeks. The roads have been bad, and farmers have been saving their apples for better prices. Pretty soon they will all be gone; then with the inquiry for them comes a scarcity, and good prices for the lucky ones. Eggs, as a rule, are low in the month of April, and the prudent poultry-keeper should bear this in mind. The turnips will probably soon bring a dollar a bushel, if they can be prevented from growing and becoming pithy. Very likely some of my readers know how to do this better than I do, and may be we raised more turnips for our market last fall than was wise. Last summer, turnips were quite a hobby of mine, and we had the first in market — yes, the first by several weeks. Shall I tell you what the result was? Why, we got a dollar a bushel at retail for our whole crop of yellow ruta-baga turnips for table use; so if we overdid the matter a little for turnips in the fall, we hit it exactly in the spring. It requires experience and brains to hit these things just right.

In regard to the price of wheat, the man who has but a few acres of land near a town or city should never think of raising wheat. Nobody ever pays extra for the *first* wheat that is brought into the market, and the wheat business properly belongs to the great prairie lands of the West. To compete with them would be folly, and it is much the same with corn. You can raise roasting-ears for market, it is true; but you can not raise corn by the carload at 25 cts. a bushel, unless that is your business. If you can raise potatoes, and have them on the market by the 4th of July, so as to get two or three dollars a bushel at retail, of course it will pay you to raise potatoes.

In regard to poultry. We have sold great numbers of Stoddard's book, entitled "An Egg Farm;" but although I have been waiting for, and watching reports anxiously, I have never heard of an establishment that raised eggs on a large scale, so they could sell them at 8 cts. a dozen at a profit. It may be done; but my impression is, it is a pretty difficult matter. Shall we give up poultry? Surely not; for every market gardener, or every small farmer as well as large farmer, needs poultry to gather up all sorts of waste food that would ordinarily be lost without them. "Gather up the fragments that nothing be lost," is a wise proverb. Last summer we had a hen that was pretty wild, and she was allowed to hatch a brood of Light Brahmas. Well, just as soon as her coop was turned over so she was at liberty, she took those Light Brahmas down to the creek; and when she got them there she just kept them there. I used to go down mornings and see them start out just after sunrise. How they did enjoy themselves among the corn and squashes, and rambling over the grounds! Did we feed them? Not at all. They fed themselves, and benefited our crops greatly. No one knows what those two broods of chickens were worth on our crops down by the creek. They cost nothing in the way of attention, nothing in the way of feed. When the old hen weaned them they roosted nights under the maple-tree; and when it came cold weather I had quite a time to get them to come up to the poultry-house and avail themselves of the advantages of civilization. People saw them as they were passing by; and before the roosters were full grown I sold them at a dollar apiece, and some of my customers went away chuckling, to think I didn't know any better than to sell them so cheap. The eggs were from a choice strain of Light Brahmas—that is all.

Now, every good-sized farm would support quite a large lot of chickens, and the feed in summer need cost nothing; in fact, you could afford to pay something to have the hens pick it up. Sunday evenings we used to take a walk down by the carp-pond, and it was one of my delights to point out to my wife and children my flock of Light Brahmas that "worked for nothing and boarded themselves." Perhaps some of the poultry-keepers and poultry-journals would ridicule such a slipshod way of raising poultry; and they may urge the danger of their being devoured at night so far away from house or home. Well, mine were never harmed, although they were near the creek, where enemies might be supposed to lurk. But should there be danger of such nocturnal prowlers, our ten-cent poultry-book gives directions for a cheap and pretty little poultry-house for just such flocks of chickens. If you are going to keep chickens in this way, of course you can keep only about so many on a certain area. I got a dollar apiece for my roosters, and they cost almost nothing. The reason is, as I told you, I started, in the first place, with some fine stock that was universally wanted. Besides the birds sold, a good many eggs were disposed of also, at 50 cts. a dozen; but I suppose everybody would have been satisfied at a dollar a dozen. After investing several dollars in one of the best male birds this spring, I am now going to charge a dollar a dozen for the eggs. Now, there is something else I wanted to say in regard to poultry; but as it starts from a different standpoint, we will take it up in another chapter.

CHAPTER XIV.

That which the palmerworm hath left hath the locust eaten; and that which the locust hath left hath the cankerworm eaten; and that which the cankerworm hath left hath the caterpillar eaten.—JOEL 1:4.

My friends, if you desire success in raising plants or in raising poultry, or in any kind of business, you have got to fight against difficulties and discouragements. Sometimes it would seem as if the odds against you are terrible odds. If you do not work carefully and wisely, you will see the work, not only of hours, but of days, swept away so quickly that it will take you by surprise and astonishment. You may have made ample provision against the effects of frost by means of glass sash and steam or hot-water pipes; but just as soon as you get a temperature just right to make the plants *boom*, you will discover that you have hit it exactly in making insect-life "boom." Perhaps the first enemy you meet will be green flies on your lettuce and other plants; and beware how you think they do not amount to much, and can not do much harm. So wonderfully rapid are their powers of reproduction, that, before you know it, they will fill your greenhouse. If you go to the books they will tell you that a thorough fumigating with tobacco-stems will kill the flies. Tobacco costs money, and fumigating takes time; and by and by you begin to fear it is more bother to fight the green flies than all your stuff is worth. If the little pests would only be so accommodating as to die submissively after you have smoked them enough, as it would seem, to satisfy any reasonable bugs, you could get along very well; but they will get sick from the tobacco, and fall down on their backs, and after a while get up again and increase faster than ever. We became almost discouraged this last winter, through this same pest; and I verily believe that the bugs would have come out ahead had we followed the directions given in the books. In despair, I wrote to our friend Peter Henderson. He told me that it is quite a hard matter to kill the flies on the leaves of lettuce when it got to making heads, for they would get down under the leaves, where the tobacco smoke could not reach them; and he said the only plan was to cover the ground with tobacco dust and then drench the plants with a tea made of tobacco-leaves. This conquered them—at least for the time; but to go over all the greenhouse in that way takes more time and tobacco than the lettuce would likely be worth.

About the first of January, for an experiment, I set one of my Light Brahmas under one of the benches in the greenhouse. Only one chick hatched out, through some carelessness on my part; but that one chick came pretty near managing the green flies, alone and unaided. When, a little later, half a dozen more spry little Brahmas came on the stage, they went over the whole of the beds, and through all the boxes of plants, and so effectually picked out the green flies in about three or four days' time that the victory was complete. Friend Terry says, in his potato-book, that the best and cheapest way to master potato-beetles is to take them off and kill them by hand. And I believe a good many others find it so. Now, after you have seen a chicken go through a greenhouse bed and snap up the insects one after another, you will doubtless decide that human ingenuity can never make a better machine for the purpose than the chicken that human ingenuity did *not* make, but that God gave, as he gave all of these other things for us to utilize. A year ago I made a similar discovery of the utility of chickens in banishing the little black flea that infests cabbages and turnips in the open air. The chickens, however, must be of the right age. In ten days after they did such execution among the lettuce they began to eat the young tomato-plants at such a rate we were obliged to keep them off from the beds, even though they chased us about and chirped incessantly to be lifted up.

Now, then, I should say that whoever goes into gardening, or starts a greenhouse or a hot-bed, wants to start, at the same time, some chickens. When you have secured a temperature right for your lettuce to grow, you have also secured a nice place under the lettuce-bed for a hen to sit; and I would start one sitting, say in October or November, and then start another every three weeks all winter long. The chickens will pay expenses by keeping down all kinds of insect-pests. They will also amuse the children, and make your greenhouse a pleasant and happy place for yourself and visitors. No hen is needed in the warm greenhouse after the chicks are three days old. Fix a warm spot somewhere for the chickens to cluster, then pick up the old hen and put her among the other fowls, and she will forget all about her chickens in a day or two, and go to laying again. Your first brood of chickens will take care of the next, and so on. When any of them get so large as to make trouble in the greenhouse, "transplant" them to the regular poultry quarters. Where chickens are wanted in the greenhouse, a hen is a detriment; for she keeps calling them down from the beds, where *they* can be allowed, but where *she* can *not* be allowed for obvious reasons. In a little time they get so busy and delighted with their work in the beds that they pay but little attention to a mother. The temperature of the greenhouse is usually so warm they need but little or no brooding. When you use chickens for keeping down the little black flea, or "jumping jack," as it is called, out in the open air, the case is different. Then, you want the mother to brood them when the weather is chilly, and to hold them to the desired spot. A convenient place for her is in the ordinary coop made in the shape of a letter A. I would, however, cover the front with poultry-netting instead of the ordinary slats. So you see poultry is going to be a necessary part of our business in market gardening. I am told that Pekin ducks will live entirely upon the refuse of a market garden, and that they will eat potato-bugs, squash-bugs, and every thing in that line. Well, we have a pair of old ducks, but ducklings have not yet made their appearance. Perhaps you would like to have my ideas of the way in which poultry should be kept, to make a sure profit and yield a sure pleasure. Very well; here goes:

HOW TO KEEP POULTRY, THAT THEY MAY AFFORD YOU BOTH PLEASURE AND PROFIT.

You may think this a simple matter; but I find it quite important that you consider well, and lay your plans wisely before you start. It is just as easy to start right as to start wrong. If you have no poultry, and never kept any, you will need to deliberate quite a little time, perhaps, before you can decide upon the *best* place to keep them. If they are going to yield a profit above what they cost, we can not afford to pay out very much money in the start; and I am glad to be able to say that not much money is needed. Although you may have plenty of time on your hands now, you are not going to have when you get things in running order. The location should first be such as to save time and steps. If you have a cow, horse, or pig, it will be economy to have the poultry quarters near these domestic animals; for when you go out to care for one you can care for all. Our poultry-house is placed between the factory and dwelling-house, so that I can have an eye on them every time I pass to and fro. If I neglect to take a look at them for a very long time, I am sure to repent it, although they have feeding-boxes and water so they are always provided with these things, whether they are visited daily or not. The poultry-house should be sheltered from the prevailing winds. It should also have plenty of sunshine. During pleasant weather there should be open sheds fronting the south, for the fowls to get out and in, and take the sun and air. Two of these sheds are very convenient—one that takes the sun in the forenoon, and the other in the afternoon. Sometimes the wind is in the east and sometimes in the west. If you give them two sheds, they can select the one of the two that will cut off the cold winds.

While poultry must have dry quarters and dry ground to stand on, they should also be as near to Mother Earth as may be, so as to get the benefit of the heat from this source.

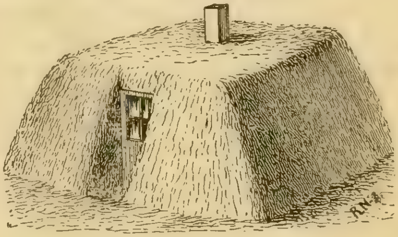
During severe winter weather, their quarters should be so arranged that they may be confined to a pretty small-sized inner room, to economize the animal heat. I discovered last winter, when the thermometer was below zero, that twenty-five large fowls like the Light Brahmas would keep such an inclosure at a very comfortable temperature, simply by the heat of their bodies. At such a time the openings may be closed about as tight as you can get them, and they will still have plenty of air.

If you can stand the expense it is an excellent idea to have the fowls so they can be shut up in a certain yard when, at certain times of the year, they become troublesome. For instance, if they get into a habit of digging up your new-made beds in the garden, shut them up until they get over it, or until the soil has, by reason of the sun and rain, ceased to look so tempting to them. They may get into the notion of eating your tomatoes at a time when it will be less trouble to shut them up than to try to keep them away from the garden.

Mrs. Root says she would not have poultry encouraged to come around the house very much. The walks around our house are sawed flagging, from the Berea grindstone quarries. This flagging looks very nice and cool and refreshing when it is kept swept off clean; but although Light Brahmas are very handsome and nice looking in the proper place, they are not just what is wanted on a nice lawn or on the walks. If their quarters are, say, 30 or 40 yards from the house they will seldom prove a nuisance in this way, unless they are encouraged to come around by bread crumbs or other food thrown out carelessly. Keep a pail in the house, called the "poultry-pail," and put the crumbs and bits from the table into this pail until there is enough to carry out to them. I like the idea of having a small plate near my own plate on the dinner-table; and when I come across a bit of food that I think is more appropriate for poultry than for myself, I lay it aside for them. Don't let any thing be put into the kitchen fire, or be carelessly thrown away, that will please the chickens. Remember they need water, grain, meat, and green stuff such as cabbage and lettuce, bones, to make egg-shells, and ashes to wallow in, etc. When you get into the way of buying ashes from your neighbors, you will find that, by sifting them with a sieve of the proper mesh, that there are lots of small bits of bone in the ashes. I was greatly surprised, in sifting the ashes we have saved up in this way, to find a splendid lot of bits of bone, burned enough so they break up very easily, just right for poultry.

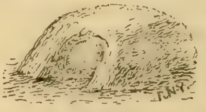
A great many ways have been devised to keep poultry-houses clean. I have never found any thing equal to peat. Draw several wagon-loads, and pile it up near the poultry-house. Whenever the ground looks untidy under the roosts, cover the untidiness with a scoop-shovelful of peat. Take a rake occasionally, and rake it all up together. This will give you a fine compost for your plants. Notice, will you, how the hens and the garden work together if you manage them rightly.

If you have only a few hens, and find it difficult to keep them as warm in winter as they ought to be, fix the place where they roost in winter, and where their nests are arranged, something like the cut below, which has been kindly loaned to me by our friends of the *Rural New-Yorker*.



POULTRY-HOUSE, PROTECTED FROM COLD BY SODS AND EARTH.

The picture gives the idea of this, so that you can modify it to suit your taste. I have no doubt such a place would be very pleasant and cozy during bleak wintry days, providing, of course, you keep it dry inside. A sub-earth ventilator would bring in air, and at the same time make a very perfect drainage, if tile were laid around the outside, to keep the water from soaking in through.



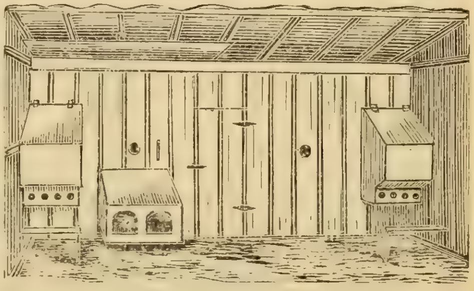
SHELTER FOR HEN AND CHICKENS.

The small cut adjoining this shows a plan for making a warm place for a single hen and chickens. A barrel is imbedded in a suitable bank of earth, being careful to have perfect drainage as heretofore. Sod it over so that the grass will help keep out the rain. When the weather is very cold, put a board before the door, and fasten the mother and brood in. They will be warm and comfortable, even during a severe freeze. If it could be managed so no dampness nor wet could possibly get inside, some chaff cushions, such as we put over our bees, might make it very comfortable for the biddy and her brood.

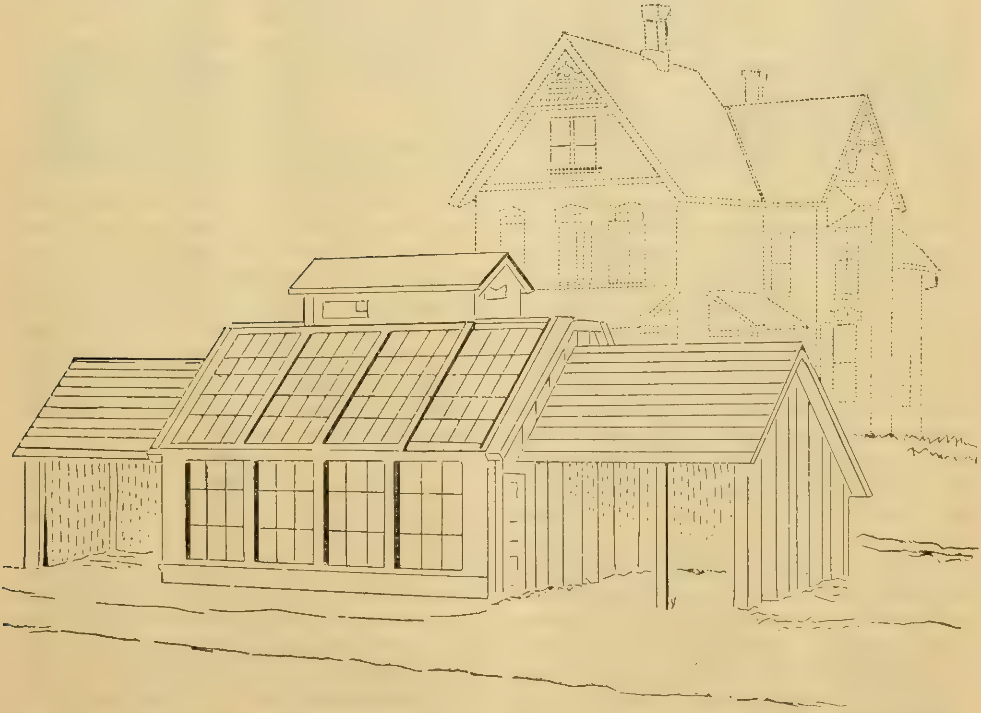
Now, unless I am very much mistaken, you who undertake to keep poultry will, unless you are naturally given to doing every thing well, experience many disappointments. Any one who is in the habit of saying, "There, I think that will do well enough," or, "Well, that is a little risky, but I guess it will have to answer," and such like expressions, will surely meet with disappointments and losses that will spoil all the profit. When I was a boy, and had nothing on my mind but my poultry, I used to succeed right along. I remember distinctly of setting a large white Shanghai hen on fifteen eggs, and getting thirteen live chickens, and I believe all were raised. Shall I tell you a little of how I have managed since I have got grown up? Well, I have set four hens this year, and the result is only four chickens. The failure in each case was because too many other things were on my mind, and I couldn't give the hens the thorough care and attention they needed. The first attempt, thirteen eggs produced one chicken. I overdid the matter by providing food for my sitting hen, so she never needed to come off from her nest at all. I didn't let nature have her own way. The next time, I took a smaller-sized hen, gave her eleven eggs, but took her off the nest regularly every day for food and refreshment, and gave her a nice place to wallow in the dust. She hatched out six chicks from the eleven eggs. The next time, a neighbor kindly offered to let me have a hen that wanted to sit, when none of mine would. To save trouble, I carried the eggs to my neighbor's poultry-house. Well, during the big snowstorm the fowls were fastened in by the snow, without food. When they could do no better they all turned upon the sitting hen and broke and devoured a part of her eggs, so I got only two chickens. The last time, a Brahma hen was allowed to sit; but a pair of Pekin ducks were left in the same yard, thinking they would do no harm. Now, although the ducks had plenty of food—corn, wheat, cabbage, and refuse from the table, they got to persecuting this sitting hen and broke all of her eggs but about three, before I knew it. A few days ago somebody broke a pane of glass out of the door of the greenhouse. They were going to repair the damage, but I told them that, during this warm April weather, it might just as well be left out. A cat got in at night, ate one chicken and killed two more, so I have only four left. Well, these disappointments were the consequences of lack of care, and letting things go in a sort of slipshod way. Now, I am going to raise a lot of Brahma chickens, just to prove that I can do it. The Brahmas are to have a yard by themselves. No ducks nor rabbits are to intrude; and when a hen wants to sit she is going to be allowed to do so in the good old-fashioned way, without annoyance from other fowls or other animals. The young chickens are to be protected by poultry-netting so no cats nor other enemies can possibly get at them. And this reminds me that mishaps and disappointments often happen because a gate or door is left open, and then something happens. Dear friends, accidents rarely happen unless some piece of carelessness permits them to happen. We are in the habit of speaking of some people as lucky, and others as unlucky. Now, I am sure anybody can be lucky with garden stuff or poultry if he tries hard enough; and if he does not try hard enough, he will surely be unlucky. A friend of mine (and she is a woman — I hope my lady readers will excuse me) succeeded in getting thirty-one chickens hatched by three hens, and thirty out of that number are now alive and doing nicely. Was it luck? No. It was simply good hard common sense and faithful care. There is no excellence without great labor.

On next page is a cut of the poultry-house I have often referred to, and which was made according to my own notion. The south roof and the south side are all glass, as you will notice, and I had it made in this way because I had noticed how nicely chickens did in a greenhouse.

The glass feature I like very much indeed. During some of the severest cold weather last winter, the fowls were cackling and scratching, and enjoying themselves in the full blaze of the noonday sun, even though the temperature was far below zero outside, and that, too, without any heat except the heat of the sun combined with the heat from their bodies. The body of the house containing the glass is 10 x 14 feet. The wings are exactly alike, and are 8 x 9 feet. They are both open towards the south, as you will notice. The eaves come down within 4 feet of the ground, so that you have to stoop a little when you go under. My reason for making them so low was to admit the sun, but exclude cold storms as much as possible. Unless the weather is very severe, the fowls will be found occupying one or the other of these sheds almost every sunny day. In the morning the sun pours directly into the shed at the right; and in the afternoon the same way with the other on the left; and one or the other of them is almost always protected from the cold winds. You have probably often noticed the way in which fowls congregate around the corner of a building, so as to avoid the wind. Well, the open sheds are made to answer another purpose still. In sultry weather the poultry seem to be happier when roosting out in the open air, or up in a tree, than anywhere else. Now, their roost is a strip of pine, 3 inches wide by 1 inch thick, and running straight through the three buildings; that is, this perch runs through the back part of each shed, and through the back part of the body of the building also. The three buildings are made of two thicknesses of inch pine, with building-paper between them; and where this perch or roost passes through the walls of the main building, close-fitting doors, large enough for even the largest Brahma rooster, are made right over the perches. In winter the fowls all roost in the warmest apartment of the main building; but as soon as the weather will permit, these little doors over the perches are swung open, and the fowls crowd out into the sheds. I wanted to see what they would do if given their choice in regard to a roosting-place. Well, I am gratified to tell you they always choose the shed when the weather is suitable, moving over to the warmer apartment only when the nights are chilly. Well, now, in this main apartment, protected by glass, we have a partition running lengthwise right under the ridge-pole. The figure below gives you a view of this partition.



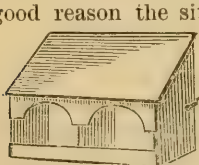
INTERIOR CENTRAL PORTION OF POULTRY-HOUSE.



OUR POULTRY-HOUSE AS IT APPEARS ON OUR GROUNDS AT THE "HOME OF THE HONEY-BEES."

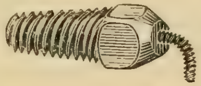
You will observe that this partition does not extend clear up to the roof. It goes up about 6 feet high, and then is covered over by means of hinged doors like lids of a chest. In the cut above, one of these doors is shown, swung open and hooked up to one of the roofs. This is for ventilation. During zero weather these doors close down tight. The door, also, in the center of the partition, is closed, making it so tight that many might think the fowls would smother; but we find by experiment, that, although 25 fowls are roosting in this little apartment, only about 3 feet wide and 14 feet long, they are quite comfortable, and the air is not by any means close so long as the temperature is below zero. A thermometer at such times will show this sleeping-apartment to be always above the freezing-point, with 25 large fowls. It must be ventilated promptly, however, as soon as the weather changes sufficiently.

Occupying each corner of the room above, and up against the partition spoken of, you will see a couple of feeders. These are made of inch boards, and screwed fast into the corner. The top is made sloping enough so that fowls can not stand on them, nor can their droppings find a lodging-place. Each feeder holds a two-bushel bag of grain. You will notice that the grain all runs down into the little trough at the bottom. The fowls have access to these troughs by means of four auger-holes. The auger-holes should be just large enough to let a hen get her head in. If too large, they will get to scattering the grain. While feeding, they stand on a perch, as shown, about a foot from the ground. Neither rats nor mice have ever found access to these feeders. Between these feeders you will notice a pair of nest-boxes. The roof of these is also sloping, for the reason given above. These nest-boxes are made large enough to admit a Brahma hen and let her turn around. The strip in front is to prevent eggs from being rolled out by accident. We prefer to have them in pairs, because, if the occupant of one nest is sitting, any hen that wishes to get in with her can get accommodations so near by as to avoid discussion in regard to who has the best right, etc. These nest-boxes are so they can be hooked against the wall wherever convenient; and if for any good reason the sitting hen is to be moved, unhook the box and carry it where you wish; or if it be desirable, the box can be dipped in whitewash or coal oil, to circumvent insects.



MOVABLE HEN'S-NEST.

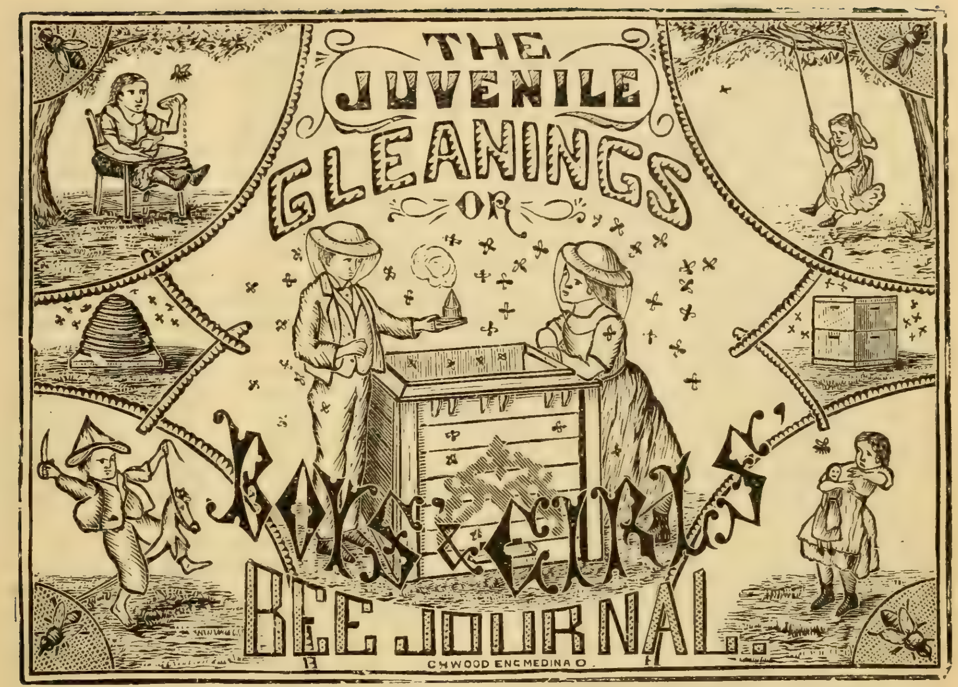
Over the ridge of the main building is a sort of cupola. This hinged ventilators, has always kept open, except in extremely cold weather. In front of the lower sash, on the south side, is a large box kept full of ashes for the biddies to wallow and dust themselves in. Provision for water I would have located in one of the sheds, in moderate weather. In cold weather it may be put in the central apartment, to keep it from freezing. Perhaps a barrel is the cheapest arrangement ordinarily at command. To let the water out about as fast as the poultry drink it, and no faster, a faucet made especially, like the one in the cut adjoining, is very convenient. It is made of brass, to prevent rusting, and tapering so it will screw into a round hole perfectly water-tight. A hole is drilled lengthwise and then tapped with a thread, so that the brass screw turns in loosely. This screw is bent at right angles, as shown, to make it convenient to turn it in or out. If you turn it so the water drips from the point of the wire as fast as the fowls drink it, it is all right.



POULTRY FAUCET.

Coarse bone meal, for the use of the laying hens, we put into one of the feeders with the grain. Gravel, whichis found by experiment to be just what the chickens want, may also be put in the feeder, to come out with the grain. The above arrangement is for fowls in confinement; but I think it an excellent plan to have similar quarters, even where they have the range of the farm. At any time when the weather is unfavorable for outdoor wandering, they can then find a comfortable retreat and plenty of good feed. You will notice that my arrangements are for giving feed, all they want, whenever they are hungry enough to hop on to the perches before the feeders. This may not be the best way for others to do, but it suits me best. Whenever I undertake to cut short the rations, I find my fowls begin to cut short the number of eggs, and I have tested it pretty faithfully with Pekin ducks. When they had all the grain they could eat every day, they laid regularly. When I shortened their rations, occasionally one or more days passed without any eggs; but they took just as much exercise, and seemed to enjoy playing in the puddles all the same, whether they had the grain *ad libitum* or not.

To be continued May 15, 1886.



THE JUVENILE GLEANINGS OR BOYS & GIRLS BEE JOURNAL.
C H WOOD ENG MEDINA O.

He that is faithful in that which is least, is faithful also in much.—LUKE 16:10.

MYSELF AND MY NEIGHBORS.

> The steps of a good man are ordered by the Lord: and he delighteth in his way. Though he fall, he shall not be utterly cast down: for the Lord upholdeth him with his hand.—PSALM 37:23, 24.

I HAVE before called attention to what the Bible has to say about enemies. David often speaks of them in the Psalms; and in the imprecatory Psalms he seems to be almost pleading with God to send calamities upon them. Then he rises above these feelings; and in one place he says, "I will not be afraid of ten thousands of people who have set themselves against me round about." The first part of the same Psalm opens up with, "Lord, how have they increased that trouble me!" Are *we* now beset with enemies the same way? In one sense I think we are. An hour ago, at the noon service, I startled some of the friends gathered there by soberly declaring, "I am sorry to say, friends, that an enemy is threatening us. We have talked of him before, and now there is no question but that we have got to fight him down."

As a matter of course, I soon had the attention of all gathered there, and quite a few looked a little anxious. Perhaps some of them wondered if we were not going to revive the subject of the burning of the warehouse, even though I had, a few days previously, asked them not to talk about it nor think of it. When they were listening anxiously, to know who or what it was, I spoke to them something as follows:

"The enemy I mean is the chap who goes around to the different rooms and takes tools away and does not bring them back; or if he does bring them back they are found to be damaged or ruined, and worthless. During the fore part of this week, Mr. F. missed his hammer, with which he embosses the rolls of our foundation-mills. This is very precise and particular work, and it is quite important that a hammer of just the right weight be used. Well, the enemy carried off the hammer; but before we could find out what he did with it, he brought it back and laid it on the bench. Mr. F. enjoyed the use of it for just two days, and now it is gone again, and nobody can tell where the chap took it.

"This morning I noticed in the tin-shop they were cutting the corners out of sheets of tin, for making the new honey-cans illustrated on page 274, by taking two snips with the shears, instead of using a pair of shears made expressly to cut out a corner at one clip. I asked the foreman of the tin-shop why he didn't use the regular corner-snips; and while doing so I took them down from the nail where they hung. The steel was chipped right out of the corner, making the tool almost worthless.

"'Why, Ned, how did this come about?' said I; and I certainly looked anxious while I spoke, and may be I looked a little cross.

"'Why, somebody grabbed them up to cut off a piece of wire. And that isn't the worst of it; for they come in here when they want a piece of wire, and always get the best shears, because they don't know how to cut wire, then go off and say nothing about it.'

"Now, friends, you see who the enemy is. Instead of going to the foreman of the room, and saying, 'I want a piece of wire so large and so long,' he undertakes to get it himself, thinking, probably, that any *fool* ought to know how to cut off a piece of wire; while the truth is, few wise men, unless they are wire-cutters by trade, know what kind of a tool is needed, and how to do it without injuring the tool. A great many people will pick up a steel wire, with too high a temper to be cut with any tool, and, seeing some shears or nippers, imagine they can do it. This enemy is just that sort of a fellow. Sometimes I catch glimpses of his coat-tails as he is just getting out of some room. Once or twice I have cornered him up, and got hold of him; but he always talks so fair, and explains so well that he didn't mean any harm, that I let him off and let it go; but with the rush of business we are now having, I am getting to be almost like David in his imprecatory Psalms. We must catch this chap, and I don't know but we shall have to put him in jail if he does not stop."

At this point in my talk, the anxious and alarmed expressions on the faces of many began to give place to a knowing look. One ventured to remark, "Mr. Root, he has got my pruning-knife." This came from the friend who sends out grapevines. Another remarked, "He has taken our rule out of our room." After the service was over, the pruning-knife came to light. The owner lent it to a fellow-workman, to cut the tops off the turnips while it was raining. He slipped it, for the time being, into his overcoat pocket; and when the sun came out, the overcoat was laid aside, and it could not be found. I told them that what was wanted was, that we should all fight against these careless ways of doing business, and all such besetting sins. We should be careful about touching a tool in somebody's else room, even though we want it only one minute; and to avoid doing damage to tools inadvertently, we should make it a point to go to the foreman, or to the proper workman, and have him do what we want done.

Now, this very matter has troubled me sorely. I have prayed over it, I have "scolded" over it, and I have sometimes begun to feel in despair, as if my project of having so many industries carried on under one roof would have to be given up as a failure, because of this enemy of whom I have spoken.

Now, friends, do you see the value of this noonday service in a factory like ours? With God at our head, and a feeling in our hearts that we are his children, it helps us to be neighbors in the truest sense of the word. It helps us to fight unitedly, and with a will, any common enemy; and it helps us to claim the promise in the two little verses at the head of this chapter about myself and my neighbors. Do you not see it so? It helps us to recognize that the worst enemies we have in this world, and the one most to be feared, are those that lurk (unknown and unrecognized, perhaps) in our own hearts, and not in the hearts of our neighbors.

GOING TO A SCHOOL EXHIBITION.

MRS. CHADDOCK TELLS US HOW SHE ENJOYED THE EXERCISES.

LAST night I went to a school exhibition. I knew better, but my girls are just crazy to go to every thing, and they coaxed me to go with them. The roads were just awful; but by driving slowly down, and walking slowly up the hills, we managed to get there at last. All one end of the schoolhouse was curtained off with three-cent calico, and they had a stage with a lounge and an organ on it, and some chromos adorned the wall. The crowd came pouring in, and every third man had a big looking-glass or a screen, or something that had to be handed over the people's heads, while dusky ghosts flitted to and fro behind the curtain.

The house was packed; there was no more standing-room, and everybody leaned against everybody because there was no help for it. I am a large woman, and am always getting smothered; and as fate would have it, I had to have a seat in the very hottest corner, where the window-fastening was broken, so that the window could not be raised. The reason I had to sit there was because none of the other seats were large enough to hold me.

The curtain parted at last, and the "school marm" stuck her head out and said, in a high thin voice, "We must have better order or we will dismiss and go home;" then when all the folks had changed feet she went on, "The first thing will be a select reading, called Betsey and I are Out." Then the American colonies fought and bled anew, and gained their liberties, with many a reference to ancient Rome. Next thing was a dialogue by two little girls, then a song by the big girls and boys. Then they read "a paper." The teacher announced "the paper" to be in "two parts;" but as a matter of fact, it was in half a dozen parts. One boy read till he gave out, then another took up the strain; and after reading all that he held in his hands he began fishing around in his pockets, and brought forth "paper" after "paper," till my head seemed to be swimming with a confused murmur of "roosters," "mustaches," "bangs," "boxes," "long-eared rabbits," and "beaux." I think I almost swooned; and when I revived, the reader was saying, "George Brown has made a hot-bed, and put his mustache into it to sprout."

I sat on the back seat; just behind me was a long bench, and it was full of boys and girls, wedged in so tight, standing cheek by jowl, that, if one of them moved it moved the whole row, and everybody said, "Don't push," and, "Look out there;" and every one looked innocent, and said, "It wasn't I."

One girl sat on fourteen different sides of me. She is a rather heavy girl, and she pulled this way and that, just as she happened to turn; and a heavy boy leaned on my left shoulder, and a slim girl leaned on my right shoulder, while a fat woman sat close up to me on the left, and a big girl, standing on the bench behind me, clasped me round the waist. The girl who sat all over me got in my lap and squashed me. I felt that I was going to die, and all the folks began to call for air, and a girl punched the broken spring with a slate-pencil and opened the window. I stood upon the seat and fanned myself with Minnie's hat. The daggers in it pricked the fat woman in the back, but she told me to fan on, she did not mind the daggers, it "felt good." It was against the rules to stand upon the seats; but I made up my mind to risk smashing the seat, and, if it fell with me, buy a new one. I'm pretty close and saving with my nickels; but when it comes to a choice between smothering to death or paying five dollars for a new seat, the five dollars has got to go. But when I stood up my feet had to suffer; they not only had to bear up my own weight, but the weight of various other people; for though my rising loosened me from one set of leaners, a new one surrounded me and leaned more heavily than the others had done, and the "heavy girl" trod on my toes and set my biggest corn to thumping, and the cold wind striking my face gave me the dancing toothache. The boys and girls with blackened faces were singing "Every day will be Sunday by and by," and I felt that every day would be Monday with me pretty soon if I did not get out of that. But there was no getting out.

Then they had tableaux, real nice ones, "Night and Morning," the "Rock of Ages," and a little fairy with long crinkly hair, and at each scene they burned colored lights and filled the house with a cloud of smoke; but at last, when the last dialogue had been acted, the last declamation spoken, and the last song sung, the crowd began to unpack itself. And when the "heavy girl" got off me, and the young man who weighed a ton took himself off my left shoulder, and the "fat woman" got off my polonaise, and the three "school marms" in front had taken their feet off my right foot, and the old lady in the black hood had released my other foot, I worked myself loose from the rest of them, and came home a sadder and a wiser woman.

MAHALA B. CHADDOCK.

Vermont, Ill., March, 1886.

BEES OF OUR OWN.

MRS. HARRISON TALKS TO THE CHILDREN ON HOW TO START IN THE BEE-BUSINESS.

BOYS and girls, I am glad to know that so many of you have bees of your own. It is said, that a person who owns his home is a much better citizen than one who rents — takes more interest in the prosperity of his neighborhood, as to roads, schools, etc.

Why, all of you who own bees are *bee-keepers*. You are adding to the wealth of our own, our native land. It makes me feel good all over to think of it. Have you made any money in the business? Veteran bee-keepers are discussing whether it pays to keep bees. Who among you will solve the problem? I wish you all had money in your pockets. Did you ever hear of its burning a hole in them?

Now I want to ask a favor of you all. It is spring now. Take an inventory of your stock—how many colonies you have, what they are worth; keep an account of your expenses — hives, sections, etc.; and when you have sold your honey, see how much you sold it for, and how many pounds you had. If you would sell your honey as Mr. Root told in last GLEANINGS how to sell lettuce and radishes, I should expect to hear that your bees paid, and that you all have money in your pockets, and shouting to your mates, "I've got money! I made it myself from my bees." MRS. L. HARRISON.

Peoria, Ill., March, 1886.

Many thanks, Mrs. H. Your remarks are just to the point, and I can heartily second all you say. We will try to put your suggestions into effect. Will the juveniles please take notice? At the close of this season, to any little girl or boy who can send in a good report as the proceeds of *his own* work and *his own* bees, we will send one of our large panel chromos, and they are beauties too. Now, some of the little folks have no bees of their own, so I hope the parents will help such by giving them a pound of bees or a whole swarm, thereby cultivating habits of enterprise and business at the start. If the father has several children interested in bees, let there be a stock company whose capital shall be a swarm of bees. This will be something like the company of Jane Meek & Brother, of whom we read in GLEANINGS. At the close of the season, when one or more swarms have been cast, the children can pay back the borrowed capital, and, very likely, have enough bees and honey left to fully pay them for their season's work.

Now, little friends, if you will tend right up to business it will not be long before you can say, "I've got money, and I made it myself from my own bees." You will then recognize the value of this money, if you ever did, and put it to some very good use. How many young enterprising bee-keepers shall we have? Who knows but that you may outrival some of the best reports of the older ones? ERNEST.

THE MOHAWK VALLEY.

HOW TO MAKE HONEY CAKE.

HAVING left my bees to the care of friends, that I might spend the winter in this historic Mohawk Valley, I have thought the juveniles might be interested in hearing of this part of the country.

Do you know that, thirty-nine miles from Albany, is a cave called Howe's Cave, a place of considerable interest? The temperature inside is always 55°.

This valley is quite remarkable as a great thoroughfare between the East and the West. Many people, and quantities of merchandise, pass through it daily. On either side are the steep hills, covered with evergreens and other trees, with bare rocks peeping out here and there. Following the road as it winds up the hill we have a fine view of the valley and the distant hills. At the left is the village of S. Below is the wagon-road, and just beside it are the double tracks of the West Shore R. R. Next is the famous old Erie canal, along which, all summer, may be seen the horses dragging the odd-looking boats through the water.

On the decks may be seen men, women, and children, and sometimes the family washing is hung out to dry as they go. In the winter the canal furnishes skating and sleighing. Beyond the canal are the flats, the river, the four tracks of the N. Y. C. R. R., where you can see a train at almost any time; another wagon-road, and then the hills again; and down these hills the streams leap and rush as though they were, indeed, hurrying to the sea.

The juveniles would find these streams, with their rocky bottoms and pretty falls, delightful places for play.

Back among the hills, and surrounded by them, is a fall of water over ledges of rocks. Near by are several houses, much too shabby-looking for this beautiful place. Near one of them I saw three bee-hives. I can learn but little of the bees about here; but about three miles away is Mr. Nellis, whom a bad boy in the postoffice caused so much trouble with the bee-keepers; also another gentleman of whom I heard it said, that he built his house and barn with money made from bees.

Near by is an old stone farmhouse with an old wood-house near it. From my cousin I learned that her father once partitioned off a little room in the chamber, put in some shelves and a swarm of bees. When the weather was quite cold they would go in and cut out honey. Sometimes it was nice and white, and sometimes not. After a time the bees died, "as all bees will." They used to make good honey cakes from the first of the following recipes. The others they do not remember to have tried.

HONEY CAKE.

Two teacups of honey; 1½ teacups of butter, a good teaspoon of saleratus dissolved in two tablespoons of water. Mix soft, with flour enough to roll; caraway seeds. Then roll them over a fancy board.

HARD HONEY CAKE.

Twelve ounces of butter, one quart of honey, a teacupful of sugar, a tablespoonful of saleratus dissolved in water. Mix this cold with flour to roll soft and thick.

HONEY CAKE.

Twelve ounces of honey, one pound of sugar, and one pound of butter; a tablespoonful of saleratus, and raisins halved and stoned.

Sprakers, N. Y. MISS L. WILLIAMS.

Your graphic description of the scenery along the N. Y. C. R. R. reminds one forcibly of the landscape and scenery along the side of the road when traveling by rail, Miss W. It has often seemed to me that those homes among the hills, with their many beautiful springs and delightful streams, must be a happy place for the children to play. The temperature of Howe's Cave seems to correspond exactly with that of Mammoth Cave, even though it is considerably further north. Now, is it not true that most caves, where they go far enough into the earth, average pretty nearly 55°?

USING THE EXTRACTOR WHILE TRANSFERRING.

REPORTED BY A JUVENILE.

WALTER got his honey-extractor about three days ago. Yesterday he made a comb-basket out of some wire cloth. Last night he transferred a hive of bees. He carried the hive into my room, and we all went in to see the fun. He then tore off the side of the hive. Their tempers began to rise, but we used the smoker and cooled them down. He cut out a piece of comb and put it in his comb-basket, and put it in the extractor and tried the extractor for the first time. He did not want to screw it to the floor, so he and Fred tried to hold it down while they extracted; but it hopped about almost as lively as a flea. Walter took out the combs and uncapped them with his razor. He declared he was going to send on for your uncapping-knife. Fred and Frank got the extractor up in the corner, and did the extracting, and handed the combs to Florence, and she fastened them in the frames. This is what I did while they all were at work: I went in there where they were at work with the bees, and stayed about ten minutes and got one sting. I thought that was enough for me, so I left the room, and about one hour afterward I got hungry for some more honey, and I went to the door and got Frank to hand me a taste of some; and before I got out of the door, another bee stung me, and I tell you I got away from there in a hurry, and did not go back there soon. It took Walter until 11 o'clock to get through with the bees. He is going to transfer another hive to-night.

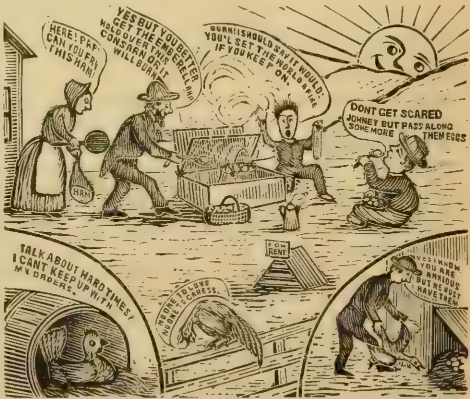
ROSALIE SOMERFORD.

Navasota, Grimes Co., Tex., Mar. 2, 1886.

"A MIDSUMMER-NIGHT DREAM."

SOLAR WAX-EXTRACTOR, AND ITS ASTONISHING UTILITY IN COOKERY.

EATING mince pies and maple sugar just before going to bed doesn't always make little folks sleep very soundly. So with friend Johnny; he lies and tosses in his bed; he thinks of every thing, and finally his mind reverts to what he has read in GLEANINGS, and he wonders why maple sugar couldn't be boiled down very cheaply in one of "them things." Why couldn't a patent evaporator be arranged so that the sun would do the whole business? He wouldn't have to chop nor carry wood any more; and wouldn't that be fine? Thinking thus he goes to sleep, and "a midsummer-night dream" creeps over him. Then he thinks his pa and his ma are cooking breakfast by the aid of old Sol, who smiles pleasantly upon the scene. But there is generally something a little inconsistent in every dream, and Johnny's was no exception. You see, the sun has just poked his grinning face over the mountains, and he would hardly have time to get the eggs boiling; but that makes no difference, for it is only a dream. Johnny has sent us a picture which tells the remainder of the story very vividly, and here it is.



HERE! PAP' CAN YOU FRY THIS HAM!
YES BUT YOU BETTER GET THE EMBERELLAND HOLD OVER THIS CONSARN OR IT WILL BURN
BURN! I SHOULD SAY IT WOULD: YOU'L SET THE WORLD AFIRE IF YOU KEEP ON.
DONT GET SCARED JOHNEY BUT PASS ALONG SOME MORE THEM EGGS
HAM
FOR RENT
TALK ABOUT HARD TIMES? I CANT KEEP UP WITH MY ORDERS.
NO ONE TO LOVE NO ONE TO CARESS.
YES I KNOW YOU ARE ANXIOUS BUT WE MUST HAVE THEM

JOHNNY'S DREAM.

Next morning, Johnny comes down stairs with eyes all blood-shot, and lids swollen. He has a pain in his digestive apparatus, and he thinks that boiled eggs are more substantial than pie and maple sugar.

ERNEST.

JUVENILE·DEPARTMENT

Every boy or girl, under 15 years of age, who writes a letter for this department, CONTAINING SOME VALUABLE FACT, NOT GENERALLY KNOWN, ON BEES OR OTHER MATTERS, will receive one of David Cook's excellent five-cent Sunday-school books. Many of these books contain the same matter that you find in Sunday-school books costing from $1.00 to $1.50. If you have had one or more books, give us the names that we may not send the same twice. We have now in stock six different books, as follows; viz.: Sheer Off, The Giant-Killer, The Roby Family, Rescued from Egypt, and Ten Nights in a Bar-Room. We have also Our Homes, Part I., and Our Homes, Part II. Besides the above books, you may have a photograph of our old house apiary, taken a great many years ago. In it is a picture of myself, Blue Eyes, and Caddy, and a glimpse of Ernest. We have also some pretty little colored pictures of birds, fruits, flowers, etc., suitable for framing. You can have your choice of any one of the above pictures or books for every letter that gives us some valuable piece of information.

> "A chiel's amang ye takin' notes;
> An' faith, he'll prent it."

I HAVE just been out watching the bees. Did you ever see them working in the rye meal, how they make their little loaves of bread, and pack them on their hind legs to carry home to their baby-bees? It is really funny to watch them; but just how they make their bread, and how they get it on to their hind legs, is a little hard to tell. I declare, after getting down on my hands and knees in the dirt, and watching with all my might, till my eyes and back fairly ached, I had to confess that I didn't know much more about it than I did before. On their hind legs the little loaf, or pellet of pollen, seemed to just grow by some sort of sleight-of-hand that almost baffled me. A bee would fasten his fore feet upon the edge of the tray, or a chip of wood, and then commence a vigorous kicking with his heels, in the white dust, all the time rubbing his hind legs together as if to grind more finely the particles of meal. Then, by some strange means, that little loaf of bread began to grow in the pollen-baskets.

Now, little folks, I want to know how it got there. I could tell, perhaps, if I watched for days at a time, but I haven't the time, and so I call upon you for help. In your letters, tell me about it. Now is a good time of the year to settle this matter, if such a thing be possible. If you haven't a tray of meal, see the A B C book, page 190, under head of "Pollen," for directions for starting the bees on the rye flour. If you don't learn any thing by it, you will find it great fun at any rate. You will see no prettier sight, and their happy hum at the opening of a new season is sweeter to me than the notes of the birds in spring. By the way, little folks, don't you believe the bees have *their* way of praising God, like the old biddy, when she sings on a warm summer's day. Perhaps they don't know from whom these blessings come, but they are happy nevertheless.

FLY-TRAPS, AGAIN.

Our little fly-trap is dead. Yes, he actually ate so much that it made him look sick. I wonder if he had the dyspepsia or the gout, or was the diet of green flies unwholesome? At any rate, the little fellow did the best he knew how, and was faithful to the end. We now have about half a dozen more to take his place, and the way they do make those naughty bugs disappear is almost wonderful. They really enjoy the fun, I believe; and when they fall off the beds they will tell us, in the best way they can, that they want to be put back on. If you should go through our greenhouse some time you would find that the plants are stripped of bugs as far as the chickens can reach; but there are not many plants above their heads, so they manage to get pretty nearly all.

ERNEST.

GOING TO MAKE A VINEYARD APIARY.

Pa has 20 colonies, and has the most in chaff hives. He has the most of them Italianized. Pa thinks the Italian bees are very kind, and exact in their work. He is going to make a vineyard as it shows in the A B C book, with a windbreak on the west side. The swarms will have a pleasant home. Last winter we made our hives by foot-power; but this winter we are going to drive it with horse-power.

Bluffton, O. NOAH WELTY, age 13.

DO BEES LIKE RED-PAINTED HIVES?

My father has 30 hives of bees, and raises a great deal of honey. He raised about 500 lbs. of comb honey in pound sections that he bought of you, and sold them from 18 to 20 cts. a pound. The extracted honey brought him 12½ cts. a pound. The bees wintered outdoors, and only one colony died this winter. The honey is mostly made from lucerne, and is of a light color. It is very good. We children like it. Do bees like red-painted hives? Father had two swarms fly into the only red-painted hive he had. Father intends to send for some queens this summer, if they can be sent by mail.

CAROLINE A. FOLKMAN.

Plain City, Weber Co., Utah, Mar. 14, 1886.

The facts you give, friend Caroline, seem to indicate that bees do like hives painted red; and no doubt red hives would be good for them in the *spring*, because the dark color absorbs the heat of the sun more than if the hives were white. I have never been really satisfied that bees notice *colors*, but I am satisfied that they can *smell*, *right well*. Last week, some hyacinths were blooming in the greenhouse; and the wind carried the perfume out of the open door. So many bees flew in and got imprisoned on the glass, that I was obliged to carry the hyacinths out in the open air. After that, not a bee entered the greenhouse.

HONEY AND BURNT ALUM FOR COLDS.

I don't know any thing about bees, but I know that honey and burnt alum is good for children when they have a cold. AMANDA STULTS, age 9.

New Helena, Custer Co., Neb.

Thank you, little friend. After our experience with the croup that I spoke of last month, I was told by a friend who has had considerable experience, that we ought to have given Arthur honey and burnt alum, the same remedy you recommend. I wonder if this is generally considered good for colds. ERNEST.

WILL AN ENTRANCE CLOSED WITH ICE DURING THE WINTER, RESULT IN DEATH TO THE SWARM ?

My pa's bees increased from 3 to 6, and gathered 110 pounds of cap honey. One of his swarms had a fly last Tuesday. When they got into the snow, the chickadees would pick them up and eat them. The entrance to one hive got closed up with ice. Would the bees have died if pa hadn't opened it? They had a chaff cushion over them. CARROLL P. MINER.

Taylor Center, N. Y., Jan. 28, 1886.

It is a little hard to say; at all events it is much safer to have the entrance in winter unobstructed, and full width. ERNEST.

A POOR CALF IS A VICTIM THIS TIME TO THE BEES.

I like bees. Papa bought two hives in the spring. He increased to 7 swarms, besides 3 which went to the woods. My papa is a brick-maker and a farmer. I have a little brother three months old. His name is Huber. Papa got the name out of GLEANINGS. I was sitting in front of the bee-hives one day last summer. One of the bees walked up my sleeve and stung me. Mamma tore my dress to get it. Papa had a calf tied under a tree near the bee-hives. Papa was working with the bees. They got cross at him and chased him into the root-cellar. Then the bees went for the poor calf. Papa went out and untied the calf, but then it was so frightened that papa could not hold it. You ought to have seen them run through mamma's garden. The onions and my pretty flowers were all alike to him.

TESSIE A. TAYLOR age 10.

Shelby, Oceana Co., Mich., Feb., 1886.

No wonder the poor calf got demoralized, and made a raid through your mamma's nice garden, and I am not sure that "more rope" would have been of very much service either. I verily believe that the next report of this kind will tell of the lusty squeals of some poor unfortunate pig that has been sticking his nose where he ought not. Bees will not, as you know, allow their homes to be tampered with; and should some burly hog poke his great snout near their homes, I am afraid our big fat friend would fare the worse. Let us be careful, little folks, of these dumb friends, and keep them away from the bees. ERNEST.

"WHAT IS GOOD FOR RATS IS GOOD FOR CHICKENS;" A NAUGHTY ROOSTER.

My pa, with his incubator and a brooder, raises lots of chickens. The rats bothered our chickens some, and pa got some poison for them. He put it under the floor, and my little brother Charley got it and gave it to the chickens. He said if it was good for rats it was good for chickens too; but it killed the chickens. I am at my grandfather's, in Galion. He keeps bees, and takes GLEANINGS. The bees were working like every thing last week. They flew well in February, and on the 11th of that month they gathered lots of pollen. Grandpa says he never saw bees do that before. He thinks they got it at the flour-mill. Last spring he had but one colony, and this winter he has seven. Grandma thinks honey and butter warmed together is one of the best things for a cold that she can get. Grandpa felt very bad when he heard of the fire you had. He heard that all your shops were burned down, and he thought he would not get GLEANINGS any more; but he was very glad when he heard it wasn't any worse. BERTIE M. MUMFORD, age 9.

Galion, Crawford Co., O., Mar. 22, 1886.

What is good for little girls is good for little boys; what is good for chickens is good for rats; but what is good for rats is *not always* good for chickens, as experience tells. Last summer the rats were eating more of the chicken-feed than the hens did. I determined that I would get rid of the nuisances, so I put some "rough on rats" in one of their holes. But the sly creatures seemed to think that what "was good for rats was good for chickens," so they pushed it out of the mouth of their hole. I happened to pass by about ten minutes after, when, lo! the large Brahma rooster was trying to get his biddies to eat some of the poisoned bread at the mouth of the hole. Quickly jumping the fence I gave one big "shoo," and made a lunge for the lord of the feast. The hens, like good biddies, ran off; but the old rooster—do you think he did? No, sir; he tried hard to swallow a big chunk of the poisoned bread. I chased him around the poultry-house, and yet he persisted in his efforts to swallow that chunk of bread. Finally, as a last resort, I "knocked the wind out of him," as the boys say. This so disconcerted his lordship that the bread shot out of his mouth. Do you think he felt grateful toward me? Not a bit of it. Like little boys who have been punished for things that they ought not to do, his wonted pride changed to an air of injured innocence. So, little boys and girls, when you have been punished for taking or meddling with things that you ought not, remember the story of the rooster, and think what it may have saved you. The rooster's punishment saved him.

Thank you, little friend, for what you say in regard to honey as a cure for colds. Our grandmas are pretty good judges of "what is good for little folks," and no doubt honey and butter will prove very effective.

ERNEST.

HOW TO PREVENT THE RABBITS FROM GNAWING THE TREES.

I would have told C. H. Sargent, page 829, 1885, how pa keeps the rabbits from the small fruit-trees, but I could not have sent him word in time to do him any good this winter. My pa slips a drain-tile over the tree. This protects it from "varmints" in winter, and does not need to be removed until the tree fills the tile. If longer tile is wanted it may be ordered at the kiln.

JAMES SHENEMAN, age 13.

Pharisburg, Ohio, March 15, 1885.

The drain-tile would answer very nicely, but I should think that they would be rather expensive; and when the trees get big the tile would have to be broken to get them off. We are not troubled with wild rabbits in this section of country to any extent; but we have had some experience with Huber's tame rabbits. During the past winter we have kept them in our poultry-yard, where are several small evergreen trees. From these the rabbits stripped the bark as high as they could reach, although they had a great abundance of cabbage-leaves and other waste vegetables. We had to send them all back to friend Fradenburg, of whom we got them. They were handsome pets, but we can not afford to have our property injured.

ERNEST.

JUVENILE PROOF-READING.

Dear Mr. Root:—I have sentences to write and correct every day at school, and I thought I would try to correct Joseph's letter, page 150. I find 26 errors.

My "intelligence" is so little, i [I] do not no [know] of any thing to write that will interest [you], but you must excuse this one, as it is the first. I like to help pa [Pa] work with [in] the bees, except such a one as that cross hybrid stock that stung pa so much threw [through] his Briches [breeches] and run him off to the spring and me under the flore [floor]. They drove the young mule colt that was 30 feet away, and made him kick and snort; his hare [hair] was long, and they tangled in it, but he soon flew [ran] away and "brade" as he run. Pa says the holy land Bees will suck 3 flours [flowers] while the i[I]talians will suck 2; he says they do not fool time away in Buzing [buzzing] a Round as the i[I]talians do. We keep sawdust 3 or 4 in. deep in our apiary; the ants and frogs will not work in it, the frogs have no place to hide as the dust keeps [keep] the weeds down; a frog will eat 50 bees, if he can get them. so much for sawdust. The Pecan [Pekin] Ducks has [have] a good chance to ketch [catch] the moth miller between sundown and dark. The ducks go among the hives every evening and ketch [catch] every miller that flies; no grass in thear [their] way, so they always lit on Pekins. every one that fly [flies]. These ducks is [are] worth keeping for this alone; besids [besides] each duck will lay 200 large egs [eggs] every year, then they weigh 15 lbs. to pare of 2 [a pair]. The feathers is [are] beautiful and white, and the meat is as nice as chicken. So come and see us and wee [we] will have a big fat one for dinner.

HENRIETTA P., age 11.

Bayou Sara, W. Fel. Par., La.

Here is what our proof-reader says :

Well, Henrietta, you have done very well indeed. Your points of order are all well taken, except three. Let us see what they are. You want Joseph to spell "pa" with a capital P. That is an error which nearly all the juveniles make. They begin by saying, "My Father keeps bees." In that case, "Father" means God; hence, pa with a small *p* is correct, except when it begins a sentence.

You want Joseph to say that he works *in* bees. That would be a very small workshop for Joseph, as well as quite a burden to the bees. Let us suppose, for instance, that we make it read, "I like to help my pa work *among* the bees;" wouldn't that be better? I think the popular prejudice would be in favor of the preposition *among*, although the same idea might be expressed in other words.

Joseph says, "Dust keeps the weeds down;" and you correct him by saying, "Dust *keep* the weeds down." Your error here is so plain that you will readily see it, so you have only 23 scores against Joseph.

But after all, Henrietta, you have left so many errors unmarked, that, if we should print Joseph's letter with your corrections, it would be just about as bad as ever; for when a coffee-pot has several hundred holes in it, and you solder up only 23 of them, it will leak as fast as you can pour water into it, and hence is unserviceable. You have paid little or no attention to the punctuation and many other features which printers are called upon to look after. If the editor thinks it worth while, we will, at some future time, reprint Joseph's letter just as we would have marked it for our regular use, and then please tell us how many changes we have made, and whether you think our changes are real improvements.

I will explain that Henrietta's corrections are inclosed in brackets so our readers will see how well she has done her work. Well, *I* think she has done pretty well, considering that she is only 11 years old. We insert the above from our proof-reader to show the amount of work required on some of our juvenile letters. As a general thing, however, you little folks send us as good copy, if not better, than many of the older ones.

ERNEST.

MAKING GRANDPA HAPPY.

I noticed in GLEANINGS for Feb. 15 a letter signed Joseph S. G. According to my count there were 24 errors in all. My brother Will has taken GLEANINGS for about two years. I read the children's letters. Papa and brother Will have 28 hives of bees. I am afraid of bees. Whenever a bee comes near me I run. My little brother Oliver Hazard, who is six years old, is not afraid of them, though. In the summer he goes all about among them, without any thing over his face or hands.

We take the following papers at our house. My papa takes two county papers. My brother Will has the *Youth's Companion* and GLEANINGS, and I take *The Ladie's Home Journal*, so you will observe we have plenty of reading-matter. There are five children in our family—four boys, and myself—two older and two younger than I.

Grandpa is an invalid. He was a soldier in the late war, and I find great pleasure in helping pass the time away by reading to him.

I lost all my my house-flowers this winter by freezing, and they were nice ones. Our canary birds are dead. The house seems different without them. I am wishing for summer to come, so I can have lots of flowers out of doors. There are lovely ferns in the woods near our house. in the summer.

LIZZIE PERRY, age 11.

Van Wert, O., March 14, 1886.

Thank you, little friend. There are one or two things of interest in your letter, to which I wish to call attention. You will see that your count of the errors found in Joseph's letter agrees very nearly with the count of Henrietta, found in another place. Notice there what our proof-reader says.—You say that you take several papers. If you read them all, you certainly will derive a good deal of benefit. One who has read considerable, always shows it; and I will say, for your encouragement, that your letter is unusually free from misspelled words But, do you know what interests me more than all? It is your kind attention to your grandpa. You say you find great pleasure in helping pass the time away for him. We always find "great pleasure" when we try to help others; and a bright-eyed little girl, such as I take you to be, can be a *great* comfort to grandpa. I remember the time when I had two grandpas, but they are both dead now ; but I have one dear old grandma living now, and her silvery-gray hairs are loved by every one. What is the text—"Honor thy father," etc.? You know the rest. ERNEST.

ONLY ONE COLONY DEAD OUT OF 300; REGULATING THE TEMPERATURE OF A CELLAR BY MEANS OF STANDING WATER.

Pa says some folks put a stove in their bee-cellars to dry them out. He puts water in, and he says it is good for them. The water has been about one foot deep in the cellar since Dec. 1st. Pa says there are 299 colonies alive, and one dead, in his cellar now.

JEANIE B. BLANCHARD, age 11.

Hilbert, Calumet Co., Wis., Mar. 17, 1886.

Well, Jeanie, you have given us a big fact in favor of a body of water in the cellar. People who have worried for fear the dampness would kill their bees, ought to be satisfied that dampness does not always prove injurious, for where can we get a better report than the one you have given us?

TEMPERATURE OF BEE-HOUSES.

Pa has two apiaries. It is a very cold winter but, pa's bee-houses are warm. My oldest sister keeps one of his apiaries, six miles from where we live. Pa has nearly 200 swarms. Pa says last year was only a "middling" one for honey. His bees are wintering well so far. Pa's bee-house is above ground, thick walls of sawdust, two upward ventilators, and one underground in each house, so he can keep them at an even temperature of 40°, which he thinks is the best. NELLIE MOFFATT, age 9.

Riceville, Ont., Canada.

KIND WORDS FROM OUR CUSTOMERS.

I will third Mr. Viallon's offer, by giving an untested queen to the one who gets the third largest club for GLEANINGS. I will also give an untested queen to the one who sends me the first $3.00 order for goods, by June 1. L. J. TRIPP.

Kalamazoo, Mich., March, 1886.

I may say, that I never lose an opportunity of speaking a good word for GLEANINGS, as well as for the "Home of the Honey-Bees;" but I believe I have already induced all to subscribe who *care* to keep posted on bee culture. The rest do not feel the want of progressive knowledge.

Independence, Cal. WM. MUTH-RASMUSSEN.

KIND WORDS IN REGARD TO TRIALS AND AFFLICTIONS.

I was very sorry to learn of your loss; but your article in GLEANINGS satisfied me that I was sorry too soon. Really, I am not glad that you are burned out, but I am glad to see you were put in such shape that you could write that article. Even Paul needed to be afflicted that he might learn "to comfort others with the comfort wherewith he himself was comforted of God."—II. COR. 1: 4.

Perrysburg, Ohio. G. A. ADAMS.

WHAT SHALL BE DONE WITH HONEY CANDIED IN COMBS?

The bee-goods, etc., ordered from you on the 22d ult. arrived in due time, and all reached us in good shape. We found every thing according to order, as we always have, since we commenced dealing with you in 1880. A five-cent article gets as much attention from you as a five-dollar one. The goods are all quite satisfactory.

Bees have wintered well here so far; they had good honey last year. What is the best way to dispose of honey that has candied in the comb?

Brady's Bend, Pa., Mar. 8, '86. JAS. SOMERVILLE.

[The best way to dispose of honey that has candied in the comb has never been agreed upon, friend S.; but you will find considerable in regard to the matter in our back volumes. It depends upon whether it is honey in sections, or honey in ordinary brood-combs. If the latter, I would make the bees use it up for brood-rearing during warm weather.]

THE RELIGIOUS TALKS IN GLEANINGS.

Your wishing your friends success, whether they patronize you or not, is something I like. The fault that some of your patrons find with GLEANINGS, viz., that it contains your sermons and religious discourses, is one thing that makes me more desirous to subscribe. I have very little hesitation in saying that, had you listened to them, you would have made a gross mistake in many ways.

Sherburne, Ont., Can. JAMES FENNELL.

GLEANINGS AN OLD FRIEND.

I can not do without GLEANINGS. It would be like parting with an old tried friend, whose smiles and voice of love awaken joyous memories of other days. The first visits GLEANINGS ever made to my home cheered me through the darkest period of my life (the last sickness and death of my young and beloved wife); its cheerful words and kind admonitions have made me better; its influence is for good. Consider me its true friend. Your brother in Christ, J. E. LAY.

Hallettsville, Tex.

HOME PAPERS AND THEIR WORK.

I am glad you are taking the liberty in your valuable journal to do some work for the Lord. Your teaching is sound and practical. Go on, brother Root; do all the good you can, and may your noble and gifted son even exceed you in the glorious work of turning people from darkness into light, and from the power of Satan unto God. I was converted about 20 years ago; but only for the past few years have I been strong enough to be a bold servant and witness for Christ. H. S. HOXIE.

Holloway, Mich.

WHAT AN ATHEIST THINKS OF GLEANINGS.

GLEANINGS is just right. If it were not so, I would try to find a paper that is. That, I call common sense. Your talks on religion suit me to a T. Although myself an atheist, I like to read and learn about all sides, if it is presented in a common-sense way. I love to read what the Christian has to say, if he only says it in a *kind* and reasonable way. I read very nearly all of GLEANINGS every number. As far as bees are concerned, I consider you good authority, and try to improve by your teachings. I take other bee-journals also. The goods I had ordered of you some time ago came all right and perfect; all gave perfect satisfaction. I shall need some more supplies this winter, and you will get my order in due season. L. W. LIGHTY.

Mulberry, Pa.

SOME KIND WORDS IN GOOD EARNEST.

Dear Friend:—Though not personally acquainted with you, I can not help regarding you as one of my greatest friends; for mainly through your kind advice in GLEANINGS I have been changed from a reckless person to a—I will not say *Christian*—but I have been earnestly trying to be one. I do not wish to take up your time, but must give you thanks, for you are justly deserving.

My bees, 20 colonies in all, are doing nicely, with the exception of one or two, rather weak. They are in chaff hives. The winter has been rather severe here. I neglected to renew my subscription for GLEANINGS, on account of building a new house, which took most of my time, and money too. My leisure hours are principally spent with bees and GLEANINGS. ALEX. SMITH.

Setauket, N. Y., Mar. 27, 1886.

[Friend S., you have made me happier by the above report than if you had told me I had helped you to become a rich man; yes, more than that. I think more of such testimonies than I do of orders amounting to great sums of money; for while the orders may help to make me rich in dollars and cents, the report indicates that my labors have helped you toward the kingdom of God and his righteousness, and this, you know, is laying up treasures in heaven. Jesus said to his disciples when they came back, "Rejoice not that the spirits are subject unto you, but rather rejoice because your names are written in heaven." And now, my dear friend, if you have confidence in my ability to still guide you, do not, by any means, stop where you are. If you are not united to some band of Christian people, go at once and tell them you want to be one of them in doing Christ's work. Do not, under any consideration, or any circumstances, neglect this. "United we stand, divided we fall."]

OUR HOMES.

Therefore I take pleasure in infirmities, in reproaches, in necessities, in persecutions, in distresses for Christ's sake: for when I am weak, then am I strong.—II. COR. 12: 10.

And be ye kind one to another, tenderhearted, forgiving one another, even as God for Christ's sake hath forgiven you.—EPH. 4: 32.

IN both of the above little verses you will notice the expression, "For Christ's sake;" and it is about the words, "for Christ's sake," I wish to speak in this talk. You know we who profess to be Christians claim to be living and working for the sake of Christianity and for the sake of the Christian religion; or, to put it short, for Christ's sake; and I suppose that you know that even the best of us waver a good deal, both one way and the other, from the straight line that would be made if we were truly working and thinking and doing every thing for the sake of Christ. It is true, we get in something almost every day, probably, for Christ's sake; but there is mixed in, and stringing along with it, a great deal that is *not* for Christ's sake. In *my* life, I should say there is a good deal that (as I review the events that have passed by), is a *good way* off from that straight and narrow line of "for Christ's sake." Somebody does some ridiculous thing, because his mind was not on his work, perhaps, or, may be, because he hadn't thought much about it, and it is my business to reprove or correct him. How shall I do it? Why, do it in such a way that it will further the cause of Christ, to be sure. It is my duty to consider well before saying any thing, whether the course proposed is going to tell directly for the Master, or whether it is going to tell some other way. I might say:

"Look here, you senseless idiot; what do you mean by fooling away your time in that way on something that is of no sort of use to anybody?"

I guess I have drawn it pretty rough, haven't I, friends? There may be people who feel *prompted* to speak like the above, but I hope there are not many who give way to such promptings. Satan does prompt just such thoughts as these. I know by experience; for sometimes, when I am worried and fretted, and find that time and material have been wasted, it seems to me as if a speech set somewhat like the above would be just the thing exactly. But I feel guilty and bad after I have let such thoughts come into my mind. It is *dangerous* to contemplate such ways of speaking. People who are addicted to profane swearing often mentally run over the words they would like to say, although they do not utter them out loud. It *is* a good thing, friends, to keep your thoughts to yourself, even if you don't do any better, at such times; but it is a far better thing not to let your mind run on such thoughts. Well, if the above expression is not the right one under such circumstances, how will this do?

"MY PATIENCE, child, there isn't any sort of need of doing that at all. Here you have wasted half an hour on something that is of little use to anybody. Do it this way."

The latter is better, and might not hurt the feelings (at least very much) of the average boy or girl who had erred in judgment. But there are some, especially those fine sensitive natures, who are very anxious to do every thing just right, who would feel a great deal hurt at even the last form of expression. Yes, I know by what I have learned, that it might cause them a sleepless night, and perhaps spoil all pleasure and enjoyment for the rest of the day. Some of you may say a little impatiently, "Why, Mr. Root, you are putting too fine a point on these things. Children must be talked to a little sharp sometimes, or they won't heed or pay any attention to what you tell them."

Well, perhaps it is true that *some* children must be spoken to sharply. I say *perhaps* it is true, for I am not quite sure in my own mind after all. The point begins to come out here, that, to be a good teacher or a good employer, is one of the fine arts. It is *indeed* one of the *fine arts*, my friends, to work constantly, daily and hourly, for the sake of the Master. Do you want me to tell you just what form of speech ought to be used? Well, I will attempt it; but you will have only *my* wisdom for it, after all. Although I have been tolerably successful as a teacher (under the great Master), there are doubtless many who could improve on any thing I could frame for such occasions. In the first place, you ought to know the disposition of the child or pupil with whom you are dealing. You ought to weigh very nicely the motives that led him to make the mistake. May be it came about because he was anxious to do every thing well; and, on the other hand, it might be because he didn't care—because the work was distasteful to him, etc. How would this do?

"Why, my little friend, I ought to have come around sooner to look after your work. You did not quite get my idea in regard to it, I see. Let me show you."

Now, some might think a part of the above sentence was a big fib, where I told him he didn't "quite get my idea," because, to tell the truth about it, the child hadn't got "within a mile" of what was wanted or expected. Well, if you are disposed to call such forms of expression "fibs," I should say such fibs are a pretty good thing. It is simply softening the form of expression so as to give your pupil to understand that the offense is not one of such great moment, even though it might be a matter of considerable loss, and the motive for so doing is, that the child may be guided to better ways in the shortest and simplest way. Scolding children, hurting their feelings, stirring up a bitterness in their little hearts toward yourself, is a long and *roundabout* way of teaching them to be clever and handy about any kind of work. *Gentleness* and *kindness* (see text), compared with the above methods, are a short cut through the troubles and trials of this world. "For Christ's sake" is a *short cut*, my friend, not only through all the difficulties and perplexities you meet here on earth, but it is a short cut from earth to heaven, to the home of the Father.

Now, in the preceding cases I have supposed we were talking to a child. Let it be "children of an older growth" for the time being. We are all of us employing somebody. You employ your grocer to keep such things as you need, and at such time as you need them. You employ the dry-goods dealer, the blacksmith, and the shoemaker, in the same way. They are serving you for wages. They misunderstand, or perhaps get lazy and indifferent; they forget; they burden you with grievous burdens, may be. A shoe that does not fit; is too heavy or too light; the meat is not fit to be sent to anybody. You don't tell the butcher so to his face, but perhaps you say it to some one of the household. What is the best way to right these wrongs? The way your good sense will dictate when you start out to do it for Christ's sake.

Paul says he takes pleasure in *infirmities.* I wonder if he meant a badly fitting shoe that pinched some tortured corn. If he got pleasure out of such an affliction, he certainly was a good and faithful servant. He took pleasure in *reproaches.* Did you ever have anybody call you names, or revile you? If so, did you look pleased? If they called you names because you were good, and because you were trying to be a Christian, you ought to have felt happy. I do not know that it would be a Christian duty to look up at your persecutor and smile, because you might thereby make him madder still, and defeat the object in view; namely, to call out his better spirit, and make him a Christian. Paul says, also, that he took pleasure in his *necessities.* Have you any necessities, my friend? Are you pinched or scrimped anywhere? Are you worried and tried? Take it for Christ's sake, and you may be serene and joyful.

May be you have been tried and vexed because there is so much time and talk wasted in this world. I grant that there are a great many false motions; that is, there is a great deal of work done that is just a form, and accomplishes nothing. There is a great deal of talk going on, too, that is idle talk. It does not do a bit of good anywhere. In these days, when economy is so much needed, how very desirable it is that nothing should be wasted! I enjoy saving. It is really a pleasure to me to get some good thing out of nothing. I like to pull up a weed and make a tomato or strawberry grow in its place. I like to take the heaps of ashes that disfigure the landscape about our homes, and make them help raise the above-mentioned strawberries and tomatoes. I like to gather up the old tinware that is kicking about — bits of hoop iron, broken crockery, and all that sort of rubbish, and put them into the reservoirs to hold water, down under that same strawberry or tomato plant. It is real fun and enjoyment to me to gather up what everybody else passes by, and make it do good somewhere. In the same way I greatly enjoy taking the surplus energy of some mischievous, meddlesome boy, and utilizing it so as to do good somewhere, instead of evil — starting him to setting out plants, for instance; give him a frame so he can set them in rows at equal distances, without any possibility of having the work look crooked and awkward, and then see him smile when you tell him how beautiful is the work of his own hands, and let him follow it out and see the good that follows from it. In almost every neighborhood we have talkative people. Their tongues get to wagging, and they so enjoy letting them wag that they never accomplish any thing anywhere. I have sometimes thought they were worse than old tinware and hoop iron. But I have found a use for them. We don't bury them to make reservoirs (their tongues, I mean), but we find them a place where somebody is wanted to do a great amount of talking. During certain seasons of the year we have a great number of visitors in our establishment. They want to look around, and they want somebody to talk to them, and tell them all about things. Now, since the new agriculture has come on to our grounds there are more things than ever before to talk about and explain. Almost anybody can show visitors around, and make it pleasant by explaining things, say for one day; but who is there who wants to go over the same thing the next day, and the next, and so on? Why, all that is needed is one of these people who are so excessively fond of talking and visiting. This love of talk comes right in play here, and is just what is wanted. Instead of getting out of patience, and calling them names, let us use these talkative propensities in such a way that they will work for Christ. Is it working for Christ to entertain visitors? Most surely it is; and where the spirit of Christ has found lodgment in the heart of a great talker, this tongue that might otherwise be working mischief is a powerful factor for Christ's sake.

Of late there is an overplus of people wanting employment. People object to going into this, that, and the other industry, because the product brings so little on the market, or because it requires such diligence and such strict economy to come out whole. One must work from morning till night to make both ends meet, and he does not get ahead even then. Yes, I know it is so; but I am inclined to think that this very thing is a part of God's plans. He wants to teach us over and over again, as he taught the children of Israel, by line upon line and precept upon precept, that there is no excellence without great labor. He wants us to learn to clip off useless expenses, useless motions, useless talk, and useless reading. My friend, if you have leisure on your hands, so that you can sit down and read from morning till night, it is a misfortune for you. I do not see how we can be good Christians unless something spurs us all the time to be throwing away the useless and selecting only the best. Pick out that which is for Christ's sake, and throw away the other. When you feel like giving somebody a big blowing-up, remember you have not time, and it won't pay. Sift out the phrases and expressions you are going to use that are for Christ's sake. Leave the rest unsaid. Then shall you have treasure laid up in heaven. Never mind feelings of spite or revenge; never mind the gratification of having "relieved" your mind. Let it go without "relieving." Say just what will do good and help the matter, and nothing more. If somebody has gone and done something wrong, be careful to decide, before you say any thing, what will help the matter; and what will *not* help the matter, let go. If the same individual is to do the same work again, he needs to be carefully instructed not to fall into the same error the second time. If, however, as is often the case, it is something he may never have to do again at all, accept the job as it is, and say nothing more about it. Never hurt anybody's feelings by complaining or criticising, unless something is somewhere to be gained by it. The fact that you will *feel* better for having relieved your mind is not to enter into the consideration at all.

Is it not true, that the reason why we fail to accomplish in a day what we have proposed is often because we have wasted time in the way I have mentioned? Instead of having labored steadily for Christ's sake, some selfish plan or selfish appetite or passion got in the way, and we stopped to indulge in that. Is not this the reason why we don't prosper in our occupation? The world sees and recognizes this spirit, and the world pays a high premium for it. Not many of us are called upon to labor as does Mr. Moody, Rev. Sam Jones, or Rev. Sam Small. The world pays homage to them because they are laboring for Christ's sake; and the world will pay deference and homage to you, my friend, if you are working patiently and solely for Christ's sake, in *your* field of labor. Let me give you an illustration.

The greatest oatmeal establishment in the world was lately located in our neighboring town of Akron, but it has recently been burned down. The proprietor, Mr. Schumacher, has for many years had a standing litigation and expensive lawsuit with a Mr. Seiberling, the proprietor of one of the great reaper and mower works in Akron. Well, Mr. Seiberling had a strike among his hands. Seventy left in a body. He employed more to take their places, but the league to which the seventy belonged threatened any boarding-house that gave them lodgings, and for a time it seemed as if the difficulty of getting a boarding-house that would dare defy the league was of itself going to prevent Mr. Seiberling from filling their places and going on with his business. At this crisis Mr. Schumacher came forward, told his old and bitter enemy that a certain hotel which he owned was at his service. "Bring on your men, neighbor Seiberling; and if we haven't accommodations enough for all of them, we will make arrangements so they can have comfortable places to stay, that you may go on with your work."

Mr. Schumacher is a Christian, and did it for Christ's sake. No doubt he rejoiced in finding an opportunity of doing his old enemy a kindness, even though that enemy had persecuted and wronged him for many years. Perhaps some of you may think that friend Schumacher was carrying the matter too far; but let me tell you that such ways of doing have been prospered to such an extent that he was worth, before the fire, over a million of dollars, and the money has all been made by honest business in the town where he first settled down when he came from Germany, a poor boy, without friends, home, or money. Now, then, was not his course in helping his enemy a short cut compared with the *usual* way of doing business? I do not know that the two are now friends; but I feel pretty well satisfied that they are on friendly terms, and probably always will be, to the ends of their lives.

A great many times, when we have difficulty something must be said. Explanations must be made, and it is well to come to an understanding with your opponent; but, dear friends, I speak from experience when I tell you to beware how you talk *too much*. Let your words be few, and let them be for Christ's sake. Look out, or Satan will get in, even at the last moment, and upset it all. I have known many difficulties to be fairly settled, when a word too much raked it all up again, and the fires of passion waged stronger than ever. While I write these words I feel myself weak and frail, and I would say helpless, were it not for the "Rock that is higher than I." When we are working for his sake he has promised to befriend us; nay, more:

> And every one that hath forsaken houses, or brethren, or sisters, or father, or mother, or wife, or children, or lands, for my name's sake, shall receive a hundredfold, and shall inherit everlasting life.—MATT. 19: 29.

SWARMING, AND AMOUNT OF INCREASE.

HOW FRIEND FRANCE MANAGES WHEN SWARMING TIME COMES.

YOU ask how much increase we make. I will give you the number from our last two years' increase. Spring of 1884, 287 colonies; fall, 455; 168 increase. Spring of 1885, 320 colonies; fall, 510; 190 increase. So you see we don't nearly double the stock. We work for honey, and keep all as strong as we can, and keep them from swarming.

When they begin to work in the spring, if we have any weak colonies we strengthen them up from the strong ones by giving them brood—getting all *strong* before we make new colonies. There is no danger of swarms coming off until there is a good flow of honey; usually about the 10th of June the white clover will begin to give a little honey, and if the bees are all strong at that time, we begin to divide. Take two brood-combs from each strong colony, and put them into an empty hive; leave the queen in the old colony; give the old hive two empty combs, if we have them: if we have no spare combs, we give them empty frames to build combs in. Now take two brood-combs from another old colony, and put them with the first two in the empty hive; take two more combs of brood from another old colony and put with the four. We now have six brood-combs in our new colony; this will make a very good beginning. With each pair of combs taken from the old colonies, take from one to two quarts of bees. If in the morning, when the old bees are mostly at home, take two quarts; but if the bees are working as strong as they usually are in the middle of the day, one quart will do, as the bees you take then are young bees that have never been out of the hive, and they will stay where we put them. We now close up the new hive for a week or ten days, until we come again. I don't mean to confine the bees in the hive so they can not get out, but just shut up the hive, and leave the entrance open so the bees can work. We go over the whole apiary in the same way, taking from one to three combs, according to the strength of the old colonies, and making new colonies of six brood-combs and six or eight quarts of bees. In a week or ten days we are back again. Now we take our extractor with us, and extract all the honey we can get. Our old colonies should be just as strong as when here before, and have as many combs. They will build two empty frames full in a week. We again take two or three brood-combs and bees as before, and fill out the old colonies with frames or combs, if we have them. The combs and bees that we have taken out of the old colonies, we use; first fill out the young ones, started when here before, to 9 combs—that is, the full size of our hives. After they are all filled out, make more new colonies of six combs. This time we cut out all but one of the queen-cells from the new colonies started when here before, and insert into each new colony, started this time, one of the queen-cells taken from those started before. Some of those cells will be accepted and hatch; some will be destroyed, and those will have cells to use when we come again. In about a week we are back, and the programme will be about the same. Taking brood-combs from the old colonies keeps them from swarming, and we keep the new colonies strong, from the brood taken from the old ones. We usually go over all about five times; but the new colonies we make, the last two rounds, we make 9 combs, a strong full hive; then we are ready for a sudden stop. The main idea is just this: Keep just brood enough with the old queens so they won't swarm; keep all young colonies strong, by giving them a proper amount of brood, and allow them only one queen-cell, and they won't swarm. Extract about once a week, then the bees have enough to do without swarming. My experience with bees is, they swarm only when they are or have been crowded during a good flow of honey. We have no trouble about swarming; we use a large hive, extract once a week, increase moderately, keep all laying queens' wings clipped, then there is no loss if they do swarm, as they will go back again.

Platteville, Wis., March, 1886. E. FRANCE.

WANTED.

MORE MAPLE SUGAR.

READERS of GLEANINGS, you ought to have seen my eyes sparkle, and heard my heart go pit-a-pat this afternoon when I came across the maple-sugar advertisement in March No. of GLEANINGS, and for sale, too, by a man in whom I had the utmost confidence—one who would not sell me an impure article if he knew it. I wish I could have you all here under the sound of my voice, and could tell you all about my little visit up there two years ago, and do it justice; then you would understand why I write this. I shall always think Providence directed me there, and I expect the outgrowth of that little visit to be a benediction to me as long as I live. But, to return to my subject. I must have some of that maple sugar in the cake, to stimulate with; if it will do as well as syrup, it is so much more convenient. I wrote you, Mr. Editor, my fears concerning my bees. I had examined but one colony, and found a scarcity of honey, and judged all the rest by that one. Mar. 16, 17, 18, I took out every frame in every hive, and I know their true condition. To my great surprise I found plenty of stores to last for some time. Surely the dear Father heard and answered the petitions sent up from time to time, to "not let them starve." I did what I could for them. Number of colonies, was 47; 1 was dead, plenty of honey, the hive leaked, and they were wet; 4 were queenless; I united them with others; all the rest were in good condition, and raising brood. I clipped all the queens that were not clipped. I am now ready to stimulate "with a vengeance," when that maple sugar comes.

With your consent I will now have a little chat with sister Harrison. Sister, your article is just what I have been wishing for, for some time. As I am one of the young sisters (only four years old in the business, and fifty in years), I am bashful when in the company of my elder sisters; but as "overcome" is one of my mottoes, I will overcome my timidity, and make a suggestion to you, in answer to your first question to the editor—"What are we to do, who have not chaff hives, and are not able to procure them?" Appropriate part of the honey money for that purpose, or sell part of the bees and make the rest comfortable.

I will now give you a synopsis of my husband's manner of wintering bees. He first tried the cellar, then the parlor bedroom, then a south room up stairs, and finally a clothes-press 8 x 10. Those four years of apiculture will never be forgotten by me. It was heavy lifting, anxious care, and loss, until I was sorry the dear Lord ever made a honey-bee. Mr. Culp then made a chaff hive. I do not know whose invention. It so far excelled the other methods that he was satisfied, but, like your barrel method, they had to be lifted in, in the fall, and taken out in the spring, and that I found to be a nuisance. When I visited Bro. Root, and saw his chaff hive for the first time, I said, "There, *that* hive is complete," and I will not rest until mine is as near like it as it can be made. Next to Root's chaff hive, I have the best arrangement for wintering bees I have seen anywhere; and the success I have is all that need be said in its favor. I have lost only one colony each winter; and when I let a colony get wet, or starve, I do not blame the chaff or cut-straw hive with it.

I would say to beginners, adopt Root's chaff hive every time. I have visited not less than 20 apiaries within two years, and find no method of wintering equal to the chaff-hive arrangement. It is such a comfort, when thinking about your bees, to feel they are comfortable—not too warm in summer nor too cold in winter; and if they want a whiff of fresh air they can slip down to the entrance and help themselves. The very thought of confining, in a cellar or bee-house, away from the sunshine, any living creature, created to go at will, is repulsive to me.

Do you not, sister, take unnecessary trouble in fixing the top part of your hive? My method is simply to examine the brood-chamber by taking out every frame. If too much honey, take out some; if not enough, give some from surplus frames saved when extracting. Put on Hill's device, a new muslin sheet, two or three thicknesses of flannels, old pieces of carpet, or old vests, pants, or coats, on top of the flannel, then chaff cushions—no using hot iron, nailing, or wire cloth.

Do not insult your bees by putting on any of these old cast-off garments without first boiling them in good strong soapsuds; then re-boil them, and rinse until they smell sweet and look clean. The more you have of these the better.

I should like to hear from the other sisters who are making a specialty of bee culture, about their method of wintering. MRS. JENNIE CULP.

Hilliard, Ohio, Mar. 29, 1886.

My dear friend, I am sure you are giving me more credit than I deserve, and I felt almost as if I ought not to let such very kind words go into print; but on a second thought I think we will let them balance some others not so kind. When somebody intimates that I am not trying to be fair and honest, I will hunt up your kind letter, and one will balance the other, and then I will go on my way, trying still harder to live at peace with all men.—The results of this past winter make me feel again as you do—that I never want to try wintering bees again on any plan that necessitates lugging them about here and there. Perhaps it may be well to say right here, that our bees have come through this past winter with the loss of only about three colonies out of 200; and the surprising part of it to me is, they were all wintered on natural stores. Not a colony needed a pound of feed after we had doubled them up and utilized the full combs set aside purposely for wintering.

WILL COLD WEATHER KILL BEES?

FRIEND NIMAN GIVES US SOME FACTS IN REGARD TO THE MATTER.

IN the winter of 1858-'9 I purchased a colony of bees in a common box hive, with a honey-drawer in the top, of 30 lbs. capacity. This hive was all open at the lower end, suspended in the open air, about two feet from the ground. In the summer, combs were extended 10 or 12 inches below the hive. The following winter, by walking past, one could see the bees clustered any day below the mouth of the hive. The first of March, middle combs were filled with brood. In warm days this brood was exposed to view for hours.

That season it issued seven swarms (last one small), and made 30 lbs. of honey. This hive and bees remained in the same position for a number of years, and it did well.

In 1852 I put a colony in a hive made of ⅝-inch boards; these wintered well for 17 years on summer stands without any other protection. I now have a colony in a hive, and this winter will make the ninth it has stood the test. This hive is made of ¾-inch boards, no other protection. It has an open space on one side, ¾ of an inch wide from bottom, to within 3 or 4 inches of the top. The comb and bees can be seen from the outside, any day in the winter.

The winter of 1884-'5 was the hardest I ever knew here on bees. One of my neighbors had some ten or twelve colonies in common box hives, no protection, and the mouths of the hives all open; that is, they stood two or three inches from the bottom-boards; they came through safe, and did well last season, while all in the neighborhood that were tucked in so very close perished. JOHN W. NIMAN.

Spring Mill, Ohio, Mar. 8, 1886.

Friend N., we have had facts, such as you give, before us for years past; but for all that, and in spite of all that has been said and written on the subject, they have never been really satisfactory to my mind. Several times lately this subject has come up, of wintering bees with the bottom of the hive left off, or, at least, a large opening in the bottom-board. Now the question is, Do these cases simply show that a vigorous colony will oftentimes get through a severe winter in spite of such exposure, or do they do better with simply a warm shell above them, and the lower part of the cluster exposed to the outside air? Do you know this comes pretty near to the point we made a while ago, about wintering bees in an inverted large-mouthed bottle?

BEE-PASTURAGE.

SOME VALUABLE AND TIMELY HINTS UPON THE SUBJECT OF SOWING ALSIKE.

SEEING the subject of bee-pasturage sometimes mentioned, I thought I would describe the way I have managed to supplement the natural supply for my bees during the last five or six years. I first tried sweet clover with but poor success, so I took up alsike clover, and this is the way I work.

About this time of the year, I buy from 200 to 400 lbs. of best alsike clover seed in Montreal, at wholesale price. This year I can get it for 12 cts., perhaps less. I expect to buy my supply next week. It will cost me ½ ct. freight, and I shall probably sell it to the farmers who are *within two miles of my apiary*, for 10 cts. per lb. At this price it is readily taken up by all who are "seeding down" land suitable for alsike, as the price in the stores here is from 16 to 18 cts. Three pounds mixed with timothy will seed an acre very well, so you see I get pasturage which will last from two to five years, of the very best quality of honey, at the small cost of $7.50 for 100 acres. I can not conceive of any plan which, with me, would be cheaper, less trouble, or that would give as quick and reliable returns. I could get a good deal of seed sown by selling it at cost; but I find that taking off two or three cents per pound makes a great difference in the amount sown. As white and alsike clover are the most reliable honey-plants we have here—very rarely failing entirely—the results have been very marked and satisfactory.

To those who wish to try this plan I would say, Work up the matter personally; canvass every farmer within two miles and more in every direction from your apiary (those living more than two miles should pay cost of seed), showing them a sample of your seed, pointing out its advantages, etc. Although alsike clover hay will not weigh so heavy as red clover, it is far sweeter and better, and all stock far prefer it to eat. One pound of seed, also, will go as far as two pounds of red clover, as the seeds are so much smaller.

Canvassing the farmers should be done *at once*, as every good farmer plans his work and buys his seed early. After you have finished canvassing, add up your orders, send to a reliable seedman, distribute, and get pay for your seed, and your work for the season is done; but it should be repeated every season, to enlarge your "base of supply" as much as possible. Of course, you will have to wait one season before the alsike will bloom.

In localities where different apiaries are near together, if the seed is furnished under cost, the parties should make up the amount of the difference *pro rata*, according to the number of colonies they have.

A WORD OF CAUTION ABOUT SOWING ALSIKE.

First, get the *very best* seed you can find. Poor seed is an abomination. Don't sow it on dry, sandy land, for alsike delights in a moist soil. Try this plan, brother bee-keepers. I think you will be pleased with the results, especially if the alsike is sown on land at all suited to it.

This simple plan of increasing pasturage may not be new, but I never heard it mentioned, though doubtless some have tried it. GEO. O. GOODHUE.

Danville, Quebec, Canada, March 30, 1886.

Friend G., I believe that whenever you write for the bee-journals you always give us something good; but the above, it seems to me, is the best suggestion we have ever had in regard to artificial pasturage. I only regret that we didn't have it in time for an earlier issue.

REPORTS ENCOURAGING.

WINTERED FINELY.

MY bees wintered finely this winter, and are starting off well this spring, although the loss of bees throughout the country has been very heavy this winter. At least one-half of the bees have died. I have the Italian bees. They are the bees for this country, as they are much stronger than the blacks.

J. W. WILLHIDE.

Webster, W. Va., March 31, 1886.

CELLAR WINTERING.

I suppose reports of cellar wintering are in order now, so here goes: My bees (95 swarms) were put into the cellar about Dec. 1st, and taken out March 26th, with a loss of only 3 swarms, and the survivors are all in excellent condition except 2 swarms, which I find by my plat-board were late second swarms. The way my bees were arranged, and the cellar prepared for wintering, I did not feel the least bit worried or uneasy about them. I am now feeding them sugar syrup, with Gray's Simplicity feeders.

C. A. SAYRE.

Sargent, Floyd Co., Iowa, Apr. 5, 1886.

PROSPECT FOR A HONEY-YIELD GOOD; BEES BOILING OVER STRONG.

Bees are humming again. They have been on the wing two days, and the weather is all that can be asked for—just right for bees. The snow is all gone and the prospect for a honey-yield is good. I think the white clover is not winter-killed, for the snow has been on the ground all winter until now. My bees came to the front 68 strong, and boiling over at the entrance; they are bright and healthy, but I will not count my chickens before they are hatched. They may not be so strong in May. JOHN REY.

East Saginaw, Mich., Mar. 5, 1886.

FROM 43 TO 90, AND OVER 3000 LBS. OF HONEY, BESIDES 100 QUEENS REARED, IN THE HANDS OF A BEGINNER.

I started with 43 swarms last spring; 20 of them were in the Viallon hive, and 23 in the old box hive. I transferred late on account of not having hives. I have now 90 colonies, about 80 heavy and strong. I extracted over 3000 lbs. of honey and several hundred pounds of comb and section honey. Honey is slow sale here. I sell extracted at 8 cts., comb at 10 cts. I have 2 bbls. on hand now. In addition to this I reared over 100 queens. I have a good Italian stock now. I think this does very well for a beginner. My hopes are not blasted by any means. In doubling my nuclei I found one late queen, not fertilized. J. J. WALDRIP.

Staples Store, Texas. Feb. 1, 1886.

Thou shalt see greater things than these.—JOHN 1:50.

A NEW DRESS.

THE *Canadian Bee Journal* now comes out dressed in a neat and tasty cover. It has just finished its first volume, and our Canadian friends are to be congratulated upon its success. We wish it all the prosperity it deserves, and that is a good deal.

ORDERING THINGS WE DO NOT ADVERTISE.

WE expect to keep in stock, ready to ship promptly, every thing we advertise in our catalogue; but where parties think proper to order of us things we do not advertise, we will do the best we can to supply their wants. But we can not be responsible for the quality or price of goods we procure for others simply as a matter of accommodation. We expect to do all we agree to do, but we can not always do what we do *not* agree to do.

THOSE BIG BARRELS.

IT is said that "figgers won't lie if you place 'em right;" and when our printers got the weight of a barrel of maple sugar 520 lbs., instead of 250 lbs., in our last issue, it showed the truth of the old maxim. After some of the last sheets were printed, we discovered that the size of the sheets of perforated zinc should have been given as 7 feet long, instead of 8, and that a whole sheet contains 16⅓ square feet, instead of 18⅔. We'll try to be more careful next time, if you will make a note of this.

A PASTEBOARD BOX, WITH A "WINDOW" IN IT, FOR HOLDING COMB HONEY.

MR. A. COX, of White Lick, Ind., sends us one of our ordinary pasteboard boxes, with a round piece of isinglass set in the front. A round hole is made through both label and box, with a suitable punch. The isinglass is then laid over the hole, and the label pasted on, holding it securely. Customers can then get a glimpse of the beautiful white comb, without opening the package. The isinglass is not easily broken, and in many localities slips suitable for the purpose could be had at a cost almost insignificant. The factories, too, where the boxes are made, ought not to charge more than a quarter of a cent each additional, to put in these little windows. I suppose the idea belongs to friend Cox.

ANOTHER SWARMING-BOX.

G. M. BISHOP, of Indianapolis, Ind., sends us a sketch of a swarming-box, made by placing a three-frame nucleus hive on the end of a pole. In front of the entrance of the hive is a broad alighting-board. This alighting-board is pushed up under the lower end of the swarm, with the hive attached. The bees leave the cluster and crawl into the hive. The whole is let down and taken where desired. The pole is made in three sections, so it can be used at different heights. No doubt this arrangement will work nicely. A frame of unsealed brood can be put in the little hive if desired.

THAT PERFORATING MACHINE.

OUR zinc-perforating machine has greatly exceeded our expectations; and while I sit here its great jaws cut out 68 holes at every stroke, or 7000 perforations every 5 minutes, so you can form some idea of its immense power. It is a self-feeder, and our machinists who made it have a pleased expression upon their faces as they watch the thing "chank," "chank," and roll out the sheets of perforated metal. The capacity of the machine is 12 whole sheets per hour, or at a safe calculation of 100 sheets per day—enough perforated zinc to make nearly a thousand tin-lined honey-boards. The very low rate at which we are offering this zinc ($1.50 per whole sheet, or 10 cents per sq. ft.) has started quite a run on it, and we hope we can supply our friends with all they want.

BUSINESS AT THIS DATE.

So far as we have been able to gather from letters received, bees have wintered unusually well; in fact, I do not remember of a season since GLEANINGS had an existence, when the reports were so uniformly favorable in regard to wintering as at the present date. As a consequence, our business is perhaps as thriving as it ever was before at this time of the year; and notwithstanding our loss by fire, by the aid of past years of experience and better machinery we are filling all orders quite promptly, with but few exceptions. Some delay was caused waiting for the machine that perforates the zinc, to be finished. Orders for odd-sized goods, those not mentioned in our catalogue, and which we do not keep for sale, have occasioned some delay.

"FOR CHRIST'S SAKE."

I WANT to add one thought here that was omitted in Our Homes. Many times in life we run on to wrongs that ought to be righted. The duty devolves upon us, and we can not escape it. The only question is, to decide how we can best do it for Christ's sake; and the point I wish to make is this: If the matter is something that is already nearly at an end, perhaps we had better permit it to go on. You may have difficulty with some one with whom you have deal: to right it may necessitate a lawsuit; but if your contract with him is nearly expired, bear with him, or put up with him for the time being for the sake of peace, or, if you choose, for Christ's sake. In the same way, many other things in life will right themselves if let alone, and, perhaps, cause less trouble and hard feeling to all parties concerned; so when you are about to disturb society, and stir up bad feeling, look the ground over carefully before you do any thing, and see if the matter will not right itself before very long, if just let alone. Bear quietly and uncomplainingly the wrongs you are suffering, for the sake of peace; and do not be in haste to bring trouble upon yourself and those about you. However, when duty *does* demand that you should bring iniquity to light, do it without flinching; but first be sure that Christ's cause will be furthered by so doing, and that the act is solely for *Christ's sake.*

A BARGAIN IN NICE COMB HONEY IN SECTIONS.

WE have just had a very pleasant visit from Mr. Gain R. Smith, of Victor, Ontario Co., N. Y. Mr. Smith says he has taken GLEANINGS right straight along since the time it was printed by wind-mill power, and he has been a bee-keeper all these years. Well, last year he produced a crop of eight or ten thousand pounds of beautiful comb honey. He sent it to the city of Pittsburg, to be sold; but as it did not go off to suit him he turned it over to his old friend Novice, who runs GLEANINGS. The honey is in neat pine cases holding 24 sections each. The sections weigh about 1½ lbs., glass and all, for every section has glass on each side of the honey, after the fashion friend Doolittle puts up his celebrated comb honey. The glasses are fastened in with tins, so they can be removed in a second. They are all filled and nicely sealed, and the sections have been nicely scraped off, so it is a handsome-looking lot; and in point of flavor it is equal to any white-clover honey I ever tasted. We offer it for sale at 14 cts. per lb. for the sections, with the two pieces of glass included; that is, 14 cts. per lb., glass and all. The sections are made of pine, so the woodwork is comparatively light. There are 171 cases in all, and the table below shows just the amount of money required for each case. It is so well packed that the entire lot came all the way from Pittsburg here without the breakage of a single crate or a single comb, and it will doubtless reach you in just as good condition. It can be shipped safely either by freight or express. If you wish, we can usually decide which manner will be the cheaper of the two.

NO. OF CASES.	LBS. PER CASE.	PRICE PER CASE.
2	33	$4.62
2	34	4.76
5	35	4.90
4	35½	4.97
8	36	5.04
6	36½	5.11
18	37	5.18
4	37½	5.25
9	38	5.32
4	38½	5.39
9	39	5.46
1	39½	5.53
31	40	5.60
3	40½	5.67
32	41	5.74
3	41½	5.81
24	42	5.88
6	42½	5.95
171		

For two or more cases we make a discount of 5 per cent; 10 or more, a discount of 10 per cent; 100, 15 per cent. The above honey is the cleanest and most perfect lot I think I ever saw. Each section is so perfectly sealed that not a bit of honey has dropped out or got daubed on the glass, and I do not believe there is a sticky section in the whole 7000 lbs.

JOB LOT OF WIRE CLOTH

AT GREATLY REDUCED PRICES.

SECOND QUALITY WIRE CLOTH AT 1½ CTS. PER SQUARE FT.

Inches Wide.	No. of Rolls.	SOME OF THE USES TO WHICH THIS WIRE CLOTH CAN BE APPLIED. This wire cloth is second quality. It will answer nicely for covering doors and windows, to keep out flies; for covering bee-hives and cages for shipping bees; making sieves for sifting seeds, etc. Number of Square Feet contained in each Roll Respectively.
24	1	1 roll of 180 s. f.
26	71	22 rolls of 217, 38 of 216, 1 of 195, 2 of 215, 1 of 210 s. f.
28	11	9 rolls of 233, and 2 of 234, s. f.
34	7	5 rolls of 281 s. f.
38	37	27 rolls of 316, 2 of 285, 2 of 317, 1 each of 632, and 215 s. f.
42	1	1 roll of 245 s. f.
44	2	1 roll of 366, 1 of 348 s. f.
46	1	1 roll of 152 s. f.
48	4	4 rolls of 400 s. f.

FIRST QUALITY WIRE CLOTH AT 1¾ CTS. PER SQUARE FT.

The following is first quality, and is worth 1¾ cts. per square foot. It can be used for any purpose for which wire cloth is ordinarily used; and even at 1¾ cts. per sq. ft. it is far below the prices usually charged at hardware and furnishing stores, as you will ascertain by making inquiry. We were able to secure this very low price by buying a quantity of over one thousand dollars' worth.

Inches Wide.	
22	1 roll 143 s. f.
24	43 rolls of 200 sq. ft. each; 1 each of 120, 168, 190, 140, 150, 140 sq. ft.
26	57 rolls of 216 sq. ft. each; 1 each of 199, 195, 201, 200, 227, 204 sq. ft.
28	73 rolls of 233, 11 of 224, 8 of 222, sq. ft.; 1 each of 257, 219 sq. ft.
30	36 rolls of 250 sq. ft.; 1 each of 235, 275, 240, 220, 227, 237, sq. ft.
32	13 of 266, 7 of 256, 2 of 253 sq. ft.; 1 each of 250, 275 sq. ft.
34	30 rolls of 283 sq. ft. each.
36	22 rolls of 300 sq. ft. each; 1 each of 288, 279, and 285 square ft.
38	1 roll each of 300 and 316 sq. ft.
40	1 roll of 233 square feet.
42	1 roll of 350 square feet.
46	1 roll of 192 square feet.

A. I. ROOT, Medina, Ohio.

JOB LOT OF POULTRY-NETTING,

In. wide.	At 1 ct. per sq. foot; 5 per cent off for two or more pieces; 10 per cent off for 10 or more pieces; 1½ cts. per sq. ft. when we have to cut it. Besides this job lot we keep in stock the regular 4-foot poultry-netting, in rolls of 150 lineal feet at same price as above. These figures give the number of sq. feet for each roll; and by dividing by the number of feet wide you can determine the length of each piece.
30	1 piece each of 15, 25, 30, 37, 65, 110, 180, 194, 258, and 265 sq. ft.
36	1 " " " 18, 18, 33, 33, 36, 39, 63, 69, 69, 84, 87, 180, 258 375, 387, 390, and 414 sq. ft.
42	1 piece each of 21, 182, 200, 210, 350, and 350 sq. ft.
60	1 piece each of 125, and 180 sq. ft.
72	1 " " " 24, 36, 42, 54, 54, 60, 66, 72, 72, 72, 138, 150, 186, 300, 450, and 552 sq. ft.

We know of nothing nicer or better for a trellis for creeping vines, than the above netting. The 6-ft. pieces are just the thing for morning-glories, and the 36-in. for sweet peas. We tried some last summer, and can speak from experience.

A. I. ROOT, MEDINA, OHIO.

ROYAL
GLUE
MENDS
EVERY THING

ROYAL ✻ GLUE.

Mends Everything.

This is the best cement we have ever tried. Almost any article mended with it will break anywhere else before the place mended. It holds honey labels on tin, etc. Ten cents per bottle; ten bottles, 90c; 100 bottles, $8.00.

A. I. ROOT, Medina, O.

FOR SALE.

One second-hand fdn. mill that will roll sheets 14 inches wide. The mill is at present in New Hamburg, Ont., Can. The original price on it was $40.00, but we will now sell it at half price, or $20.00.

Also one exactly like it, owned by W. W. Bliss, of Duarte, Los Angeles Co., Cal. There is nothing wrong with these mills, except that the rolls are of smaller diameter than those we now make, in consequence of which they do not make quite so thin fdn. right in the middle of the rolls as those made now with rolls of a larger diameter. They will, however, roll narrow sheets equal to any, and will roll sheets a foot wide; but when of so great a width, the center is a trifle thicker, as explained above.

Also one 9-inch Dunham mill, second hand. The mill has, however, been completely fitted up, painted, and varnished, and is, to all appearances, both in looks and quality of work, equal to a new one. Price $20.00. The list price of a new mill of this kind is $40.00.

Also two 10-inch mills of our own make, that were taken from parties who were wanting mills of longer rolls. These have been finished, and we pronounce them in every respect almost as good as new. Price $15.00 each.

Also one 10-inch mill, Olm make, fixed over so as to do about as good work as it ever did. Price $12.00. **A. I. ROOT, Medina, O.**

A NICE LOT OF **GOLDFISH** now ready for sale. Order from W. L. McINTIRE,
7 8 9 Mt. Vernon, Ohio.

PURE ✧ ITALIANS ✧ EXCLUSIVELY.

STOP, ❋ READ, ❋ AND ❋ ORDER.

Having determined to devote my time and attention exclusively to the production of pure Italian bees and queens, during the season of 1886, I offer, in order to reduce stock, **50 Choice Colonies of Pure Italians** in 10 Langstroth frames, guaranteed to contain at least 4 full frames of brood and 4 lbs. of bees in new chaff hive, at $10.00 each. I append my prices for the season.

My terms are cash with the order. First orders will be filled first. I will refund money at any time a customer may become dissatisfied with waiting.

My methods: One kind, and the best of that kind. Nothing except tested queens sold at any price. I will send one-year-old queens until stock is exhausted, and then this season's hatch. I will commence to send, about May 1st.

1 tested queen	$1 00
1 pound of bees	1 00
1 frame of brood and bees	1 00

1-frame nucleus, tested queen	$2 00
2 " " " "	3 00
3 " " " "	4 00
4 " " " "	5 00

In lots of 5, five per cent discount; in lots of 10, ten per cent discount. In lots of 10 or more nuclei or pounds of bees, I will pay express charges for the first 1000 miles. Now remember, I guarantee safe arrival and absolute satisfaction in all cases. Sample of live workers free by mail. Capacity, 25 queens per day after May 1st.

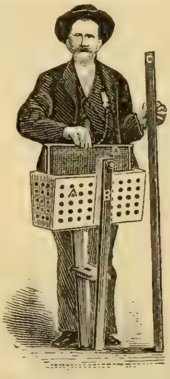
ABBOTT L. SWINSON,
PROPRIETOR,
GOLDSBORO, Wayne Co., N. Ca.

Importer, breeder, and dealer in the finest bees in America. All cells built in *full colonies.* No queens reared in less than 3 L. frame nuclei. Satisfaction, or money refunded. American Albino Italians (the finest and best bees I have, from home-bred mothers; a well-acclimated strain of Italians, and perfect beauties); Syrians and Carniolans of first grade. Imported mothers from F. Benton. Untested queens, *warranted purely mated.* May, $1.00 each; June to Oct., $1.00 each; 6 for $5.00. Fine tested queens, May, $2.50; June to Oct., $2.00 each. Nuclei, 75 cts. each, L. frame, bees and brood; bees by pound sent only in nucleus of one frame, brood and honey, each, for $1.00 a pound, price of brood to be added. I guarantee safe arrival. Foundation 45 and 55 cts. (*clean and pure*), per pound.

Choice breeding queens, of my American Albinos, $5.00 each. Send 10 cts. for sample workers, and be convinced. Rev. Lewis Werner, Edwardsville, Ills., April 4th, says: "The *American Albinos* are the *finest* I ever *saw.*" Friend Chas. F. Muth says: "They are well worthy to be bred." I make a *specialty* of *fine American Albino* Queens and *Nuclei.* 9d



KALER'S Swarming - Box.

No more CUTTING LIMBS! No more ABSCONDING SWARMS! No more CLUSTERING of TWO swarms TOGETHER! No more HARD WORK to HIVE SWARMS! EASILY done, QUICKLY done, and WELL done with KALER'S SWARMING - BOX! Made of GOOD MATERIAL! READY for USE, at $1.00 each.

Made to SUIT ANY SIZE of FRAME, by

W. S. KALER,
Andersonville, Indiana.

Send postal for description. In ordering Box, give name of hive and size of frame used.

DUNHAM AND VANDERVORT FOUNDATION

We have a large stock of choice yellow beeswax, and can furnish Dunham comb fdn. for brood comb, cut to any size, for 40c per lb. Extra thin Vandervort foundation, 46c per lb. We guarantee our fdn. to be made from pure beeswax, and not to sag. Will work up wax for 10c per lb., and 20c per lb. for section.

Recent Additions to the Counter Store.

FIVE-CENT COUNTER.

1 | MARKET-BASKETS. These are much better made than those we have been selling heretofore, and they are packed for shipment, 10 in a nest, with the handles loose. By this means they will go at a much lower rate of freight than formerly. We are enabled to make the prices by the tens and hundreds as follows: ⅛ bushel, 10, 35 cts.; 100, $3.00. ¼ bushel, 10, 38 cts.; 100, $3 25. ½ bushel, 10, 40 cts.; 100, $3.50. At the above prices, double-pointed tacks are included, for tacking the handles. We can send samples by mail where desired, at a cost of 8 cts. for the ⅛ bushel, or 10 cts. for the ¼ bushel. We hardly need mention the thousand and one uses for a light, pretty, and stout market-basket.

FIFTEEN-CENT COUNTER.

6 | BENCH-VISE. . . . . | 1 40 | 13 50

This, though, small, is a little beauty, and wonderfully handy for any one who likes to fix things up. The jaws are one inch wide and the vise is 3 inches long.

TWENTY-FIVE CENT COUNTER.

6 | CARPENTER'S BEVEL, or try square... | 2 00 | 18 00

Can be set at any bevel. Finished with rosewood handle, blade 8 inches long.

THIRTY-FIVE CENT COUNTER.

3 | RULE, TWO-FOOT, 6 fold . . . . | 3 00 | 25 00

This is oftentimes more convenient than an ordinary four-fold rule, because it shuts up so as to go in the vest-pocket without any trouble.

A. I. ROOT, Medina, O.

Names of responsible parties will be inserted in any of the following departments, at a uniform price of 20 cents each insertion, or $2.00 per annum, when given once a month, or $4.00 per year if given in *every* issue.

$1.00 Queens.

Names inserted in this department the first time without charge. After, 20c each insertion, or $2.00 per year.

Those whose names appear below agree to furnish Italian queens for $1.00 each, under the following conditions: No guarantee is to be assumed of purity, or anything of the kind, only that the queen be reared from a choice, pure mother, and had commenced to lay when they were shipped. They also agree to return the money at any time when customers become impatient of such delay as may be unavoidable.

Bear in mind, that he who sends the best queens, put up most neatly and most securely, will probably receive the most orders. Special rates for warranted and tested queens, furnished on application to any of the parties. Names with *, use an imported queen-mother. If the queen arrives dead, notify us and we will send you another. Probably none will be sent for $1.00 before July 1st, or after Nov. If wanted sooner, or later, see rates in price list.

400 Lbs. (about) of *Thin Foundation*
still on hand. The lot, 43c per lb.; 100 lbs., 44c; less, 45c. Few lbs. more brood at 35c.
9d H. L. GRAHAM, GRANDVIEW, LOUISA CO., IOWA.

KIND WORDS FROM OUR CUSTOMERS.

CHAPTER 12—HIT THE NAIL SQUARE ON THE HEAD.

Friend R., we want to say that never, in our experience, have we read so good a chapter as No. 12, page 220, GLEANINGS, March 15. You hit the nail square on the head. I believe hundreds will thank you for it. With best love and wishes.
R. C. TAYLOR.
National Cemetery, Fort Scott, Kans., Mar. 24, 1886.

"THE OLD ROOT AND THE ROOTLET."

I appreciate your efforts to give us the latest and best pertaining to bees, carp, etc., and now as the young "Rootlet" has come to the assistance of the "old Root," I presume the tree of knowledge will take a boom; in fact, it has already started, and I wish it success. C. R. SCHMELTZER.
Scholl's Ferry, Oregon.

HOW WE DO OUR JOB WORK.

Friend Root:—I have had hundreds of dollars' worth of printing done within three years, and consider myself a good judge of job work, and can say that the work you did on my "First Principles in Bee Culture" is very fine, and fully meets my expectations. G. K. HUBBARD.
La Grange, Ind., March 20, 1886.

A KIND WORD FOR GLEANINGS AND ITS WRITERS.

Received the goods all right and in excellent condition, packed by "Bert." They were eleven days in transit. I just got my freight bill, $1.13; reasonable enough for 125 lbs., the distance they came. I am highly pleased with them. Every thing comes together exactly right and true to measure. I am a practical carpenter, but I can buy of you far cheaper than I can make. As you seem to be criticised on the moral part of GLEANINGS, permit me as a subscriber to say that part is very welcome here. I was sorry to see friend Hutchinson disagree with you, for I like his writings in GLEANINGS very much. The information he gives is worth more to me than I pay for GLEANINGS. And then Doolittle—well, his contributions are second to none, in my estimation, *sub rosa*, not even to Novice himself. Now, as you have so many to cater for, you must expect to step on some of our toes. Personally, I chew tobacco; there you step on my toes; do I complain? Not much; you are too light to hurt. I believe you think it wrong, but I don't. I read your articles, however, for I like both sides of a question. I think you are doing as you wish to be done by; only give us the amount of bee-information we get now, and I won't complain.
Cape May City, N. J. GEO. W. BLAKE.

HOW SHALL WE KEEP THE BOYS AT HOME.

The opening-up of these diversified industries on the farm not only gives employment to persons of different tastes, but makes country life more attractive, and will do much to answer the question so often asked, "How shall we keep the boys on the farm?" Your Home Papers have been helpful to me, and I heartily sympathize with you in your efforts to conduct your business on Christian principles. WM. C. COOMBS.
Lindale, O., Apr. 4, 1886.

GET ABOARD AT THE RIGHT STATION.

I have been reading your A B C book, also some of your old journals, and found *them* very interesting. I have only one swarm of *Italians*. I wish to increase my stock. I want a through ticket, and wish to get aboard at the right station; therefore please find inclosed one dollar for GLEANINGS for this year. R. E. HARPER.
Hartsgrove, Ashtabula Co., Ohio.

THE EDITORIAL "WE."

Friend Root:—I am glad to see that neither you nor our *Ernest* young friend, who bids fair to be his father's worthy successor, is addicted to what is sometimes called the vice of "wegotism." I like to see any one, even if he be an editor, give his own opinions on his own responsibility, and not cover it up with a *we*, and it seems ridiculous for one who has reached the position of a "stump speaker," or for an editor of a one-horse county paper, to speak as if he represented a large and important constituency. You have my hearty sympathy in regard to your loss. BURDETT HASSETT.
Howard Center, Iowa.

EXCELLENTLY PACKED.

Please excuse me for not letting you know before this that the goods purchased from you came to hand all right. I have examined every article except the comb foundation, and have found them all right, and am much pleased with them all. They were excellently packed—not a single thing either broken or scratched by shipment. I am much pleased with the A B C book. Its being in the form of a cyclopædia makes it very easy to find just what we want at any time; and as to GLEANINGS, I do not think a person could invest an honest dollar in any thing else that would pay him better. Please accept my sympathy on account of your recent loss by fire. FIRMAN TETTEMER.
Montgomery City, Mo., Mar. 29, 1886.

KIND WORDS OF SYMPATHY BY A FELLOW-SOLDIER —OLD JACK.

It was with deep feelings of regret that I read of your heavy loss of property in the loss of your warehouse and contents, and the cruel loss of your old family servant "poor old Jack;" but I think I should rather be in your place than in the shoes of that poor miserable specimen of humanity, with the remorse of conscience that he must carry through life, although it seems sometimes if such a thing could be possible, that some folks were born without any conscience, or had lost the very small one they might have possessed. I am glad that your factory and lumber was spared, and that you are going to be able to fill all orders; and I hope the friends will all remember you in your misfortune, and give you their orders, and will all be blessed with good luck with their bees, so they will prosper and need to send good large orders. May the Lord ever bless you, and keep and prosper you, both spiritually and temporally, all of your days; and may you finally receive the reward of the righteous, is the best wishes of your friend and fellow-soldier of the cross. D. H. ALLEN.
Birney, Pa., March 29, 1886.

[Poor faithful old Jack! After giving a life of almost twenty years of faithful service to our family, letting each new baby learn to drive by holding his lines, and learn to ride by trying to sit astride of his great broad back; after carrying the whole family, singly or collectively; after pulling boxes and packages through the mud, or our whole factory, almost, and never flinching, poor faithful old Jack lost his life by the burning of our warehouse, Mar. 7, 1886. He was the special property of my wife, having been raised by her father; and now the only memento of this faithful old servant is a blackened horseshoe. May God help us to remember these household treasures while they are with us.]

OUR $1.00 FORCE-PUMP.

The goods shipped me the 16th were received to-day, and are all right. The pump was a surprise to me, for I did not expect so perfect a one for the money. Many thanks for the favor.

Nichol Junction, Mo. WILL T. ZINK.

DOTH JOB FEAR GOD FOR NAUGHT?—JOB 1: 9.

Mr. Root:— I once felt a little vexed at you, as I honestly thought you had not dealt fairly with me concerning an advertisement I sent for GLEANINGS. I then used language like this: "I once had some faith in your religious pretensions. I now find I was deceived." Since that I have watched your course, and am now satisfied that your intentions are honest, and that your Christianity is sincere, hence I will humbly beg pardon for having used the language above quoted. I have met a number of bee-keepers who have, like myself, at some time in the past had serious doubts as to your Christianity, believing you were pursuing this course for the sake of the "almighty dollar;" but I think almost all of them are now convinced that you are consistent with your profession. I thought I would feel better mentioning this matter, and have all right in the sight of God.

JOHN A. BUCHANAN.

Holliday's Cove, W. Va., Jan. 23, 1886.

HONEY COLUMN.

CITY MARKETS.

MILWAUKEE. — *Honey.* — Recent receipts of honey on this market give now a very fair supply for customers for either comb in sections or extracted, and we can quote choice 1-lb. sections at 17@18c; 2-lbs., 16@17c; extracted, in kegs or tin, white, 7½@8c; dark, 6@6½c. *Beeswax*, 25c. Demand fair.

April 26, 1886. A. V. BISHOP,
142 W. Water St., Milwaukee, Wis.

KANSAS CITY.—*Honey.*—Market firm for 1-lb. sections at 15@16c., and very little on the market. 2-lb. sections, 10@12 cents; California the same. Extracted, dull and on demand, 3@5 cents. *Beeswax*, 22 cents. CLEMONS, CLOON & CO.,
Apr. 20. Cor. 4th & Walnut St's., Kansas City, Mo.

CINCINNATI.—*Honey.*—No new feature whatever on the market. Trade perhaps duller than usual. Manufacturers are seeming to take a rest. Prices are nominal, and no changes to note from last quotations. *Beeswax.*—There is a fair demand for beeswax, which we quote at 20@25c on arrival.

April 21, 1886. C. F. MUTH & SON,
S. E. Cor. Freeman and Central Avenues,
Cincinnati, Ohio.

CHICAGO.—*Honey.*—The demand for comb honey is good, and the supply of choice grades is scarce. Prices range at 16@17c for fancy; extracted shows little change, and demand light. *Beeswax*, steady at 25c. R. A. BURNETT,
April 21, 1886. 161 S. Water St., Chicago, Ill.

BOSTON.—*Honey.*—There is no change in prices, and rates are a little slow. BLAKE & RIPLEY,
April 21, 1886. 57 Chatham St., Boston, Mass.

CLEVELAND.—*Honey.*—The market continues bare on 1-lbs., best white, which would bring 14@15c on arrival. Best white 1-lbs. are selling at 12@13. Old, 8@9. Extracted, 7@8. *Beeswax*, 25@28.

April 20, 1886. A. C. KENDEL,
115 Ontario St., Cleveland, Ohio.

ST. LOUIS.—*Honey.*—Choice comb honey has good inquiry. We quote white clover at 14@16c. Basswood, 12@12½c. Buckwheat and Spanish needle, 10@11c.

Extracted slow at 7@9c in cans; 5@6 in bbl. Dark, in bbls., is selling as low as 4c.

Beeswax.—Finds ready sale at 21c for good stock, though the supply is liberal.

April 21, 1886. W. T. ANDERSON & CO.,
104 N. 3d. St., St. Louis, Mo.

DETROIT.—*Honey.*—The market is almost bare of comb honey, with but little demand, however, at about 14 cts. for best. *Beeswax*, scarce at 25c.

April 21, 1886. M. H. HUNT,
Bell Branch, Mich.

BEAUTIFUL
FOUNDATION

And very choice all-in-one-piece **SECTIONS,** V-groove — wholesale and retail, and exceedingly cheap. Send for Samples and Free Price List of every thing needed in the apiary.
(Near Detroit.) M. H. HUNT, Bell Branch, Wayne Co., Mich.

SECTIONS,

$3.50 per M. Dovetailed, all-in-one-piece. Send 2-cent stamp for sample. **E. S. MILLER,**
9-12db **Dryden, Mich.**

CARNIOLAN
QUEENS & BEES A SPECIALTY.

Send for Descriptive Price List and Circular.

(Formerly of Spring Hill.) **Decatur Co., Ind.**

In Order to Introduce my Golden Italians

And place them within reach of all, I will send untested queens for 90 cts. each; ½ doz., $5.00; 1 doz., $9.50. Tested queens, $1.75 each. My queens are reared from an imported mother, and in full colonies; 2-frame nuclei, with untested queen, $2.50; 3-frame nuclei, with untested queen, $3.00 (on Simplicity wired frames). Full colonies, Italians, in 8-frame Simplicity hive, $5.50. Full col. hybrids, $4.00. Ref. A. I Root. Address **A. B. JOHNSON,**
9tfdb **Clarkton, Bladen Co., N. C.**

CONVENTION NOTICES.

The next annual meeting of the Michigan State Bee-Keepers' Association will be held in Ypsilanti, Dec. 1st and 2nd, 1886. All are cordially invited. H. D. CUTTING, Sec.

Clinton, Mich., Apr. 24, 1886.

The Central Michigan Bee-Keepers' Association will meet May 18, 1886, with Capital Grange, at their hall in North Lansing, at 10 o'clock A. M., to hold three sessions, forenoon, afternoon, and evening. All bee-keepers, and those interested in bee culture, are invited to attend, and to bring or send hives and fixtures, and any thing of interest to bee-keepers. For any special information, address the secretary,

North Lansing, Mich. E. N. WOOD.

As per notice previously given, the bee-keepers of Stark and adjoining Counties met in Grange Hall, Canton, O., Apr. 13, 1886, and organized the Stark Co. Bee-Keepers' Society. A very pleasant and profitable meeting was had, and there are prospects of great good being done the cause through the instrumentality of this society. The next regular meeting will occur on the last Tuesday in August. MARK THOMSON, Sec.

Canton, Ohio.

The Keystone Bee-keepers' Association will meet at Court-House in Scranton, Pa., on Tuesday, May 11, 1886, to elect officers, transact important business, and listen to the able papers of Messrs. G. M. Doolittle on the production of comb honey; L. C. Root on the production of extracted honey, and the Dadants on queen-rearing and general management. Come one and all, and make this meeting the best of all.

Clark's Green, Pa., Apr. 2, 1886. ARTHUR A. DAVIS, Sec.

CIRCULARS RECEIVED.

The following have sent us their price lists:

S. W. Morrison, Oxford, Pa., an advertising sheet—Carniolan queens.

Geo. F. Smith, Bald Mt., Pa., a 4-page list—apiarian supplies.

Hemphill & Goodman, Elsberry, Mo., one-page list of bee-supplies—specialty, the Ideal Reversible hive.

M. H. Hunt, Bell Branch, Mich., an 8-page list of bee-supplies in general. Mr. Hunt is every bit an energetic business man, and we note with pleasure the consequent growth of his business since he began.

C. A. Stillman, Hornellsville, N. Y., a 6-page list of bee-supplies.

J. C. Mishler, Ligonier, Ind., an advertising sheet of Italian bees and queens.

Jas. M. Denham, Valley, Ky., an advertising sheet of bees and poultry.

B. Davidson, Uxbridge, Ont., a 4-page price list—bee-supplies and fanning-mills.

The following were printed at this office:

J. B. Hains, Bedford, O., an 8-page list of apiarian supplies in general.

Jos. D. Enas, Napa, Cal., an 8-page circular of bee-supplies.

I am being asked my opinion of the new circulars Mrs. Cotton is again sending out quite plentifully. The statements she makes, and the prices she charges for the goods she sends out, would, in my opinion, forbid her being classed with our regular supply-dealers, to say nothing of the strings of complaints against her that have filled our bee-journals for years past.

GLEANINGS IN BEE CULTURE.

DEVOTED TO BEES, HONEY & HOME INTERESTS.

Vol. XIV. MAY 1, 1886. **No. 9**

TERMS: $1.00 PER ANNUM, IN ADVANCE; 2 Copies for $1.90; 3 for $2.75; 5 for $4.00; 5 or more, 75 cts. each. Single Number, 10 cts. Additions to clubs may be made at club rates. Above are all to be sent TO ONE POSTOFFICE.

Established in 1873.
PUBLISHED SEMI-MONTHLY BY
A. I. ROOT, MEDINA, OHIO.

Clubs to different postoffices, NOT LESS than 90 cts. each. Sent postpaid, in the U. S. and Canadas. To all other countries of the Universal Postal Union, 18c per year extra. To all countries NOT of the U. P. U., 42c per year extra.

NOTES FROM THE BANNER APIARY.

No. 77.

THE WINTERING PROBLEM.

IN the article quoted last month from Mr. Quinby, it was apparently shown that the feeding of sugar did not prevent diarrhea. Mr. Quinby did not say so, but it is presumable that there was bee-bread in the combs, and that the bees were wintered out of doors. Such being the case, the trouble is easily accounted for, at least by some of the leaders in the "Pollen Theory," by saying that the temperature was so low that the bees sought and consumed the bee-bread.

Dr. Joslin says that the temperature should be kept about 40° in the fore part of the winter, in order that the bees may remain in that quiet state that Mr. Clarke calls hibernation, which is so conducive to their health. Later in the season, when they have commenced breeding, and are more lively, he would raise the temperature, *a la* Boardman, to 45°, or perhaps 50°. I do not know but I agree with this. I would say, however, that some of my colonies were *nearly* as quiet when I took them from the cellar the middle of April as they were in December. Dr. Joslin says, that "bees will not eat pollen when kept warm enough," hence the theory vanishes. Yes, but suppose they are *not* kept warm enough, what then? And suppose that the honey is full of nitrogenous matter, what then? No one has claimed that pollen would cause dysentery among bees unless they consumed it. How shall we prevent its consumption? is the question. Shall we remove it from the hive, or is it possible to keep the temperature at such a point as to prevent its consumption? Perhaps a combination will answer. We will bring the bees through, to the close of the honey season, in nearly a starving condition, feed them sugar, then *keep them warm.* I have just been back and read Mr. Doolittle's account of how he warmed up his bee-cellar, by artificial heat, to 50°. It was in the fore part of the season that he did this. I can not help wondering if the result would not have been different if the heat had been used in the latter part instead of the fore part of the winter.

You say, Mr. Editor, that your use of artificial heat proved disastrous in the house apiary. At what degree was the mercury kept, and at what part of the winter was it employed? I have been corresponding with Oliver Foster. He says his house-apiaries are from *warm* to *hot* according to the ventilation, and during the past winter he has lost only 2 colonies out of 296. He has tried sub-earth ventilation in connection with house-apiaries, and abandoned it on account of expense and *uselessness.*

I put 25 colonies in my cellar, under my kitchen, last fall. Some had natural stores, some sugar stores, some *no* bee-bread (*one* was overloaded with it), some were comparatively free from bee-bread, some were prepared early, some late, some later, and some *latest,* etc. The temperature was variable. It would average about 45°; in fact, there is where it was most of the time. Some cold mornings it would be found at 38°; in two hours, however, it would be back to 45°. *Two* mornings it was at 35°. In warm afternoons it would run up to 50°. There is only a single door between the cellar and the outer air. The cellar is damp. It was visited several times a day, sometimes with a light. Quite a good many bees came out and died upon the floor. One colony was queenless, tried to raise another, raised some drones, and died. The one having combs overloaded with bee-bread perished with diarrhea in its worst form, although it lingered until nearly spring. This is, perhaps, hardly a fair test, as the combs were selected, and were so full of bee-bread that it didn't seem as though there was room to store the sugar syrup. It was fed early. Others may have succeeded in feeding bees late, and in preparing them for winter late; or, rather, they may have been successful in wintering bees thus prepared, but I have not *usually* succeeded. I commenced last year, the first of September, to prepare bees for winter. Every few days I would prepare a colony or two. All those prepared in September, with the exception of the one that had so much bee-bread, and the one that was queenless, came through in good condition, with no distinction between natural stores and sugar; but all those that were fed or prepared for winter in October, either died or were so weak that they were nearly worthless. Two of them died, and the rest were united until I have only 17 colonies left. Those colonies that were prepared late did not seal their syrup. There were *slight* traces of dysentery in the colonies fed late. W. Z. HUTCHINSON.

Rogersville, Genesee Co., Mich.

Friend H., when we used artificial heat in the house-apiary it was kept warm by our lamp-nursery, and the heat was used in the spring of the year, during March and April. I do not remember the temperature, but I think I aimed to keep it about 60 or 70°, that the queens might extend their brood-nest without being in danger of getting chilled. The lamp-nursery answered the purpose of keeping the building warm, even when it was cold and frosty outside. It started moth-worms nicely in empty combs, but it didn't seem to help brood-rearing much. With the experience I have since had in raising plants in the greenhouse, I think I might do better; but I believe we can raise all the bees we can make use of by cheaper means than the use of artificial heat.

SETTING THE BEES OUT OF THE CELLAR.

A DIALOGUE.

"GOOD morning, friend Doolittle. I called to see if you had set your bees out of the cellar. I heard yesterday that you did not practice setting your bees out as early as some of us do."

"No, I have not set the majority of mine out yet, friend S., and I don't see any object in getting them out before there is any thing for them to do. They only waste away in their fruitless attempts to get sap from the sap-buckets, water from the cold brooks, and by trying to rob from each other. By leaving them in, this loss, vexation, and robbing are avoided, while the colonies are much better for the season's work. Have you set yours out ?"

"Yes: I set them out more than two weeks ago, for I thought I must, as I read in one of my agricultural papers that bees should not be left in later than April 1st."

"Have you had any trouble with their robbing ?"

"Yes, plenty of it; and I called to see what I could do about it. The paper said, that after the bees were out they should be fed a little in the middle of the day, so as to stimulate brood-rearing. So I went to feeding, and I have had an *awful* time."

"Well, if that is what you have been doing, I don't wonder; for I tried that plan of feeding years ago, and I, too, had an awful time. It seems strange to me that such advice should get into print when all bee-keepers must know, it seems to me, that such a course is sure to 'raise a row.' If you feed at all, the evening is the time to do it, feeding about sunset on warm evenings, and about dark on cool. The reason for feeding at dark on cool nights is, so that no bees will get lost by flying out, as feeding always excites the bees to activity; but, lest I forget it, I will tell you what I do to stop robbing when the bees get started at this time of the year. As soon as I see that a colony is being robbed I close the entrance so that only one bee can get in or out at a time. This keeps the robbers from getting much honey, and allows the bees from the hive to get in. At the close of the day I set a comb of honey in the robbed hive, if I think they have been robbed short, and set the hive in the cellar, leaving it there until pollen is plentiful from elm and soft maple, at which time there is little danger from robbing, as the bees now care more for pollen than any thing else. Now return the colony to its stand and all will be well."

"When will you set your bees out?"

"When the before-mentioned trees get in blossom, so that the bees can do something to advantage, which will be in a few days now, if the weather holds warm as it is this morning."

"One other thing I should like to know, and that is, how you keep the bees from stinging you when you are setting them out. I got stung fearfully while setting mine out. My hives have loose bottom-boards, which I do not carry into the cellar; and upon setting the hives out, the bees would begin dropping out, when they would get in my clothing, or anywhere they could, and then sing and sting."

"I know how this goes, having often had a trial of it; and of all the wicked bees to sting, those which drop from the hives at such times beat any except the Cyprians. Besides, there is quite an item of loss here; for all these bees which drop out, mark their location where they drop, and are lost."

"Yes, I noticed that part; for in carrying out one hive I came near dropping it close by the entrance of the cellar, which caused a lot of bees to get out, and they hung around there all day, ready to sting me every time I went near."

"Exactly; and now I will tell you how to prevent both loss and stings. Just outside the cellar-door place a wide board, and close by place your smoker, all ready smoking. As soon as you get to the door of the cellar with the colony, set it on the board and immediately puff some smoke under the bottom. Now close the cellar-door and place the hive on your spring wheelbarrow, puffing in a little more smoke at the bottom of the hive. Wheel to the stand, and you will lose no bees nor receive any stings. This also keeps the bees from all rushing out pell-mell, and thus less confusion results."

"A spring wheelbarrow! What do you mean?"

"Do you take GLEANINGS?"

"Yes."

"Well, I mean just such a one as the latest one pictured in that paper."

"Do you set your bees all out at one time, or on the same day?"

"No: I set eight or ten out in the morning of a pleasant day, as soon as the mercury marks 45° in the shade, and then as many more at about 4 o'clock in the afternoon. In this way there is no chance of robbing or mixing, as these hives are scattered about in the yard while but very few bees are flying from any save these hives, and all gets quiet before night or the middle of the day."

"How about setting the colony on the same stand it occupied the season before?"

"I pay no attention to this; for by scattering them about, and using the plan I do, all mark their new location perfectly."

"Well, good morning, as I see you are in a hurry."

"Good-morning. Call again."

G. M. DOOLITTLE.

Borodino, N. Y., Apr. 17, 1886.

DEVELOPING A HOME MARKET.

NO NEED OF SENDING OUR HONEY TO THE CITY MARKET.

IN his article in GLEANINGS for Apr. 1, page 276, J. H. Martin says: "These low prices are facts we have got to face." Now, what is it that causes these low prices? Perhaps some will say, overproduction; but I think this is a mistake. I believe that the present low prices of honey are caused more by producers neglecting their home markets, and sending the entire crop to the large markets, than by overproduction.

I wish that village of 10,000 population which friend M. speaks of were near here. I think I could show him that honey could be sold there, and at a better price than in New York or any other large market. In two small villages near here, of about 1000 population each, there was sold, last season, over a ton of honey, netting the producer about 13 cts. for comb, and 11 or 12 cts. for extracted. In these same villages, a few years ago, scarcely a pound of honey was sold. We have also sent honey to other villages along the line of the A. & S. R. R., which has netted us about the same price. As friend M. says, when a bee keeper has several tons he can not work it all off in this way; but every pound that is sold in country villages is one pound less to be sent to the large markets, which are almost always overstocked.

I know that it costs something to develop a market in country places; but I believe that it pays in the long run, for we get a line of customers that are reliable, and can be depended upon year after year. We have customers who purchase whole cases (30 lbs.) at once, for their own family use, and their children do not "get sick," neither do they "stop short off," as long as we supply them with a good article of well-ripened honey. Our experience has been, that there is always a demand for the best; but a poor article sells slow at almost any price. Some merchants refuse to sell honey at first. They get an idea that it is bad to handle, and will daub their other goods; but they can usually be induced to try it when they see that it is put up in neat attractive cases, and that it is convenient to handle.

Since we can not compel people to buy our honey, we must try to produce nothing but a first-class article in evey respect, and then spare no pains to put it up for market in the most convenient and attractive manner possible.

Afton, Chenango Co., N. Y. O. G. RUSSELL.

TRUTH BOUND TO PREVAIL.

TURNING THE TABLES.

FOR the last three winters, after selling my own crop of honey I have been selling for bee-men in Wisconsin, Iowa, and Illinois. Yes, the train-men would roll off the 500-lb. barrels, right in broad daylight, for me. It was not long till it was reported that Lindley was selling artificial honey. I know it has made me feel sad to know that people would think so. Some thought I was deceived in the honey; but I have gone on with my business, and I am glad to say that my trade is on the increase, and falsehood is giving way to truth; and I have gone from place to place teaching the people that bee-men do not make honey, as stated in the papers. Yes, I have gone to nearly every house in a city of 15,000 inhabitants, holding up the banner of truth for the bee-war. If I have made but little money, I hope that the bread I have cast on the waters will be gathered many days hence.

Sometimes when I feel weary, and trade is dull, I think of the day that is not far off when, instead of selling from 3 to 50 lbs. at a place, I may sell 200 or 300 lbs. or more. Now, this is the point I want to make: That those of us who are poor, and need money to pay our debts, should not wait for some one to send for our honey, paying us a small price for it, nor that we should send it to the city to glut the market there. On the contrary, let us take a sample, go right out among our neighbors, and teach them to use honey, even if it does take work. Some, I know, are too proud to do this sort of work; but, "He that humbleth himself shall be exalted; but he that exalteth himself shall be abased."

Now, when we get every small town, as well as the large ones, well supplied with good honey, and the vast multitudes in the country taught the truth in regard to honey, then I think it is time enough to talk about "too much honey" raised. Yes, brother Root, I think the day is not far off when we can sell honey to large numbers of people who now use none.

I have been in the bee-business six years. I have not done much at it, I know, yet; but it has been my own fault, mostly. I shall not give it up, but press on by the help of God.

In one of our daily papers the other day I saw something like this: That the honey sold by J. R. Lindley, of Georgetown, was examined by Prof. Cook, of the Agricultural College, Lansing, Mich., and pronounced pure honey. Doubting parties sent a sample of the above honey to friend Cook. Yes, I shall show the public that my honey is pure.

Georgetown, Ill., Mar. 21, 1886. J. R. LINDLEY.

Thanks, friend L. Your suggestions are excellent, and they apply not only to disposing of a honey-crop, but to any sort of a crop. It is everybody's business to use all proper means to dispose of his produce, whether he is a manufacturer, farmer, gardener, or bee-keeper. And there is one thing I especially like about this matter of going around among your neighbors with what you have to sell. It opens the way for pleasant and friendly relations in your whole community; and where one is seeking the kingdom of God and his righteousness, as I am sure you are, by the Scripture texts you give us, it gives him a wonderful opportunity to work for the Master. By all means keep your neighbors thoroughly posted in regard to your produce and what you have for sale.

BOOK-REVIEW DEPARTMENT.

SIMMINS' NON-SWARMING SYSTEM.

BEFORE me lies a copy of a little work bearing the above title. It is an English production, written by Samuel Simmins, Sussex, England. It contains 64 pages, concisely setting forth the system as therein described. Briefly, the system, when comb honey is the object, is this:

Just prior to an expected honey-flow, crates containing sections filled with *comb* previously built out are placed over the brood-nest. These crates are not tiered one above another, but are of such a size as to be arranged horizontally, side by side. So far the method is similar to the one advocated by Walter B. House and others a few years ago; that is, that the sections must be in readiness, filled out with new empty comb.

Mr. Simmins discourages the use of heavy foundation in the brood-chamber, claiming that it is a useless expense. This will probably accord with the views of Messrs. Doolittle and Hutchinson, as expressed by them a short time ago. In the lower story, Mr. Simmins reduces the number of brood-combs to about half, filling out the empty space in front of the entrance with empty frames without even foundation for starters. He claims that the brood-chamber, as thus arranged with the filled sections above, does away with swarming altogether; that the bees coming in heavily laden with honey, on finding no convenient place to store the honey in the brood-chamber, will carry it above into the sections, filled out with comb. The author further claims that he thereby secures the advantages of contraction, yet allows the bees a large amount of room. In order to continue this state of affairs he keeps the upper story well supplied with sections filled with comb; and if the bees should build comb in one of the empty frames (which he says they rarely do), he cuts it out and places the same in the sections. The whole secret, he says, is to give plenty of room. So much for the non-swarming system.

IS NATURAL COMB CHEAPER THAN THAT PRODUCED FROM FOUNDATION?

Among other things, the author, as before stated, does not recommend foundation for the brood-chamber. His reasons for so doing are, that brood-comb can be produced more cheaply by the use of raw sugar, and empty frames. There are many of us who are ready to take issue with him here. According to the experiments of Prof. McLain recently, and others in former times, it takes 20 lbs. of syrup to make one pound of wax. When syrup is 5 and 6 cents per lb., it looks as if combs made in this way were pretty expensive. To put it in Prof. McLain's own words, in his report for 1886 he says, "Estimates can easily be furnished to prove that the production of every pound of wax costs the bee-keeper ten times the sum realized from its sale." Mr. Simmins does not, however, disparage the use of foundation in the surplus-department. In fact, the comb filling his sections is first built from foundation.

In regard to reversible frames, the author can see no real advantage to be gained from their use, notwithstanding his American cousins have said so much in their favor. After numerous experiments, he says that, in his opinion, many of the reversible frames now in use will, in a short time, remain unreversed.

While there are some things we would criticise in this little work, a careful perusal of the same will convince us that there is much that is valuable as well as practical in its pages. Its teachings are not strictly new, but they are presented in a rather new light. I do not know the price of it, but I presume it could be purchased for a small amount, of the publishers, T. Pettitt & Co., 22 Fifth St., London, W., England. ERNEST R. ROOT.

WINTERING IN CELLAR AT HIGH TEMPERATURE.

EXPERIMENTS IN REGARD TO SAME.

FRIEND Miller's report, page 22, has been the means of my attempting to give my experience in cellar wintering. I shall not attempt to answer all of friend Miller's questions in regard to what is the best temperature for cellar, etc., but I will give my experience for the last four years.

I have made bee-keeping a bread-and-butter business for the last eight years, and have never lost over 8 per cent in any one year, but have had experience in what we will here term high-temperature cellar wintering for only four years. Previous to eight years ago I had kept bees in connection with my farm, the bees getting attention when there was nothing else particularly urgent for me to do, and during that time it was my custom to winter in the cellar; and I always noticed, about the middle of March, when the temperature began to rise, my bees would get uneasy, just in proportion as the temperature rose, and it then seemed to me that if I could keep the temperature down to 40 or 45° all would be well; but I found I was not equal to the task. After making bee culture a study and business, devoting my entire time and efforts in that direction, it occurred to me that, if the little pets would keep quiet, why not give them about 60° in the early winter, and keep the temperature there? Would it not be as well?

About that time friend Barker gave his experience in high-temperature wintering, and I arranged my cellar to give the new theory a test. I now put my bees in as near the 15th of Nov. as I can, and leave them in until those packed in chaff bring in pollen plentifully. The bees in the cellar are quiet—as much so in April as in February. I have no occasion to give them a cleansing flight, which I used to think necessary when they were in a cold cellar. I keep the temperature as near 65° as I can (and it seldom varies more than two or three degrees), and I notice that many strong colonies cluster on the outside of the hive, yet seem very little disturbed when entering the cellar with a light, which is my custom to do quite often. To avoid running too much risk in any one place I have been in the habit of dividing my bees in two or three lots of nearly the same number of colonies, and packing the strongest lot in chaff, and putting the others in cellar and clamp; but after four years' experience in burying in clamps I have discarded that method entirely, as I find (with me) it is not only uncertain but very untidy as well. The last three years I have not lost a single colony out of 115 wintered in the cellar, while I lost about 5 per cent of those packed in chaff.

Last winter, to give a fair test, I reduced the temperature to 48°. At 52° the bees wintered nicely, but were somewhat uneasy in the spring, and were set on their summer stands two weeks earlier than the two years previous, and the result was spring dwindling; and although we did not lose any, yet all were weakened to a greater or less extent. I had in January 117 colonies in the cellar, with the thermometer marking 65° during the cold wave, while it was 16° below, outside. Now, the principal advantage I receive from a high temperature is, less honey consumed, which is quite an item with me. I can leave my bees in the cellar very much later in the spring than I could at 40°, thereby in a great measure avoiding spring dwindling. Why they do not dwindle seems evident enough to me; but my theory may not be correct; therefore I will leave others to draw their own conclusions. From these facts I also find that nearly all will breed in the after part of the winter, and thus some of the weaker colonies actually come out stronger than they were when they went into winter quarters. Friend Miller asks, "Should our cellar gradually become warmer toward spring?" From my past experience I should answer no, but keep the temperature as even as we can. I never care how much pollen there is in a hive, as I never had a case of dysentery when the temperature did not get below 50 during the winter. Now, Bro. Root, I learn by the bee-journals that this question was pretty well discussed at the Detroit Convention, but it seems to me we are keeping the temperature of our cellars too low; also, I fear, we are too cautious about putting too great a number of colonies in one cellar; and it is my belief that bees need but very little air in winter; and I would modestly ask if we are not inclined to give them too much draft during their winter repose. I have given my experience, hoping that some who have not been as successful in wintering as myself, may be benefited thereby; and if such should be the case I shall feel amply rewarded.

A. E. WOODWARD.

Groom's Corners, N. Y., Jan., 1886.

Friend W., this matter of wintering bees at a temperature of from 60 to 65 degrees was a good deal discussed in Detroit, and it is one of the puzzling things about bee culture. After we had got it laid down in the books as beyond question or controversy, almost, that the temperature of the cellar should not be much if any above 50 degrees, here we have, at this late day, quite a number who practice and recommend a temperature of 65 degrees, or even higher. If the bees can be kept quiet, and be made to stay in their hives, or even on the outside of their hives, no doubt it will be a saving of feed.

SOME NEW-OLD MATTERS.

RED-CLOVER QUEENS; JUGGING BUMBLE-BEES.

SOME new old matters are being discussed over again, I see. Noticing advertisements as well as reading matter, I could not but smile when reading *red-clover* queens and *red-clover* bees for sale by two or more dealers. Visiting the blooms of red clover belongs to all the yellow races of *Apis mellifica*.

Is not Dr. Arwin, page 587, 1885, mistaken about queens being produced in 8 days from starting of cell? I think Dr. Gallup, when living in Iowa, several years since, made the same mistake. I have reared thousands of queens, at all seasons, from early spring to late autumn, and have never yet had a queen emerge from the cell in 8 days from the starting of the cell.

I agree with Mr. Searcy, of Griffin, Ga., in all he says concerning the "Mt. Lebanon" strain of Syrian bees. He could have said more in their favor, and some non-desirable qualities. A cross with the Italians takes most of the ill temper out of them, and adds to their size and beauty. They have some good qualities not possessed by the Italians. I like them.

And Bro. Wm. F. Clarke is about to become almost converted to clipping queens' wings, and says that one argument he has used is, it disfigures the queen. Without reference to back volumes of the bee-journals, if I remember correctly, he argues that the continual clipping of queens' wings would ultimately result in a feeble or wing-deformed progeny—that it was barbarous, and in keeping with the same ignorance as plucking geese, etc. His arguments were from wrong premises. I have not yet discovered that it interfered in the least with the queen's value, or that of her progeny, to clip off the wing. In fact, in performing the operation, just as I would give the scissors the clip, the queen would, in turning round and round, get one foot, or one foot and part of the leg, between the scissors, and off it would come too. I have kept such for more than one season, without seeing any ill effects from the amputation.

And you, Mr. Editor, say in foot-notes on the article on jugging bumble-bees, you never had any faith in it, because it seems so unreasonable. In Moon's *Bee-World*, Vol. 3, p. 175, you may find the same method for trapping them. A brown or blue jug is as good as a black one, Mr. Root, and will capture them. After one or two get in and get to buzzing, they pour in like sheep going through a gateway. In my boyhood days, one of the amusements of the schoolboys at recess, or after dismissal in the evening, was fighting bumble-bees and breaking up their nests. From ill usage our old wool hats had "gone to seed," so to speak, elongated, with a hole in the top. With the face well protected and neck tied up with handkerchiefs, the enraged bumble-bees were sure to plunge into the hole in the top of the hat, and were not in a hurry to get out.

From your report, and that of others, I was not a little surprised at the large trade there is still in the queen-supply business. Eight or ten years ago one would have thought that by this time everybody and everywhere would be supplied with the new races of bees; but it seems the business is enlarging and increasing. One of the boys last winter got me shifted on a side track in business, and I reared but few queens as compared with former years. But I am at home now, and will be in the apiary all the time, and will be in the bee-business in all its branches the coming season. Some of the pleasantest and happiest days in years gone by were spent in watching and working in the apiary and vegetable-garden. Work (not too hard) gives a relish for one's meals and sound sleep. And you have but little idea what a pleasure and satisfaction it gave me when I used to send you by mail, one, two, or three dozen queens, and receive a postal acknowledging the same, with the remark, "The queens were lively as crickets,"—" fine, "or " good " or "satisfactory," or something of the sort, and "not a dead bee in the cages."

When you again come within one hour's ride of my home, as you did on your trip to New Orleans, I will just say the latch-string hangs on the outside; and although you might find things loose around, as though a widow lived here, nevertheless you'd be welcome, and we should like to see you.

W. P. HENDERSON.

Murfreesboro, Tenn., Jan. 18, 1886.

Several have reported queens hatched in eight days from the time of the starting of the cell. If I remember correctly, I think we have had such cases in nine days. Is it not possible, under some circumstances, that a worker-larva of just the proper age might be changed into a queen in eight days from the time brood was given to a queenless colony? —You are right, friend H. Many of these things have been discussed for years; but a new generation has sprung up since GLEANINGS was first started, and the matter is new to them, if not to the veterans. The matter has been very fully discussed as to whether clipping queens' wings could result in wing-deformed workers. I think those most capable of judging decided that the matter would have to be carried on for ages, and even then might not affect the wings of the workers at all.—I am very much obliged for the additional light you give us in regard to the black-jug bumble-bee trap. If they go into the hole because they hear their comrades buzzing inside, and if the color of the jug has nothing to do with it, it puts quite a different phase on the matter, and I have no doubt but that you are right.—In regard to the queen-business, almost any business will enlarge and increase if the manager keeps himself in readiness to fill orders promptly every day in the year. We don't quite do that, but we come pretty near it on queens and bees—at least, so near it that people have got into the habit of saying, "If you send to Root you will get your queen by return mail;" and a good many of the brethren know by experience, that, when they send to some others, and those, too, who advertise pretty extensively, they may have to wait not only days but sometimes weeks. Friend H., it gives us pleasure to receive queens with not a bee dead; and as I have told you before, there is another thing I greatly enjoy; that is, handing over the cash to those who are helping us to be prompt to our customers.—I am sure I was not aware that I was within one hour's ride of one of our old friends and patrons. Had I been, I fear I should have been a trifle uneasy about passing you by.

A COLONY THAT WOULD NOT ACCEPT OF A QUEEN.

ALSO A COLONY THAT WAS QUEENLESS FROM THE 10TH OF AUGUST TILL THE 14TH OF APRIL, AND STILL WINTERED ALL RIGHT.

THE 10th of Aug., 1885, I removed a queen from a colony of bees. They at once started cells. On the 10th day from the time of removing the queen, or on the 20th of Aug., I destroyed all cells and caged a laying queen over the frames. After being caged 24 hours the bees acted well disposed to her, and I liberated her. In a few hours, I looked and saw that she was there all right unmolested. Next morning she lay in front of the hive dead. I then examined thoroughly for a cell or a hatched queen, thinking I might have missed one, but I could find none, and so I caged another queen over the frames. They acted kindly toward her, and in 48 hours I liberated her. The bees seemed to receive her well. In a few hours I examined the colony, and she was walking leisurely over the combs, the bees seeming to take no notice of her. Next day I looked carefully in front of the hive, but could see nothing. The next day I examined, expecting to see eggs, and found the queen on the bottom-board dead. Then I went over them thoroughly, but could find nothing that had any signs of a queen, but I decided there must be one and so I waited two weeks.

At the expiration of that time every thing remained the same. I then put in a frame of hatching eggs, but they started no cells. Then I went over them again, then tried another queen, with the same result. Fairly disgusted with them, I let them alone. When I put my bees into the cellar there was about a quart of them, perhaps three pints. I set them in, and, to my surprise, this spring, the 14th of April I found nearly as many, apparently, as last fall. I set them out, gave them a thorough looking-over, but could find no queen or eggs. I then gave them a frame of hatching eggs, but they started no cells; and as I had some surplus queens on hand I tried it again. They accepted the queen, and she is all right.

Now, what should have caused that colony to be so obstinate? Has any one had a case like it?

HOW I WINTERED MY BEES.

I put into a room 10 feet square, made of matched boards, without any ventilation, 75 colonies — 20 strong, 20 fair, and 35 rather light; temperature ranged from 45 to 55°. I removed them Apr. 14 and 15, with the following result: 18 extra strong, 35 good, 14 light, 4 too weak to recover, and 6 dead outright.

J. B. MASON.

Mechanic Falls, Me., Apr. 17, 1886.

Friend M., the case you mention is rather unusual. I should still be inclined to think there was some sort of a bee in the hive, which the bees recognized and treated as a queen. This would account for their refusal to accept queens, or to build queen-cells; but I may be mistaken in the matter. The most important fact brought out by the above report is, that this quart or three pints of bees lived from August till April. As these were all old bees, and *quite old* at that, we should like to have you tell us if there was any difficulty about their feeding their larvæ and taking up the general work of brood-rearing.

THE FIRM OF JANE MEEK & BROTHER.

A Serial Story in Ten Chapters.

BY REV. W. D. RALSTON.

CHAPTER V.

SPRING WORK.

AT length the snow melted away from around the parsonage, and every thing indicated the approach of spring. Mr. Meek, as he conducted family worship one morning, read from the second chapter of the Song of Solomon: "Lo, the winter is past, the rain is over and gone; the flowers appear on the earth; the time of the singing of birds is come, and the voice of the turtle is heard in our land; the fig-tree putteth forth her green figs, and the vines with the tender grapes give a good smell." He remarked, "Surely these words describe the pleasant spring-time. How grateful we should be that this pleasant, happy season is now at hand!"

After they had arisen from kneeling in prayer around the family altar, Tommy said, "If spring is at hand, our bees ought to be out to enjoy it."

His father replied, "We will set them out to-day, providing it proves as fine a day as it now promises." The day was fully as fine as could have been expected, and at ten o'clock Mr. Meek went to the cellar, lifted the nail-keg hive, and, gently carrying it into the yard, placed it where it had stood in the fall. After being so long imprisoned in darkness, the bees enjoyed their flight very much, and filled the air as though swarming.

Mr. Meek judged from the weight of the hive that more feeding would be necessary. The children again put their spare cash together and bought fifty cents' worth of sugar, which was made into a syrup, and fed in the same manner as in the fall, only more sparingly, with a view to stimulate brood-rearing. The bees were safely through the winter, and preparation might now be made for the summer's work.

One day the children accompanied their father to town, and went with him to the shop of Mr. Woods, the man who made bee-hives. He showed them samples of the different hives made by him. They were all well made, and nicely painted. Reading Mr. Langstroth's book led the the children to select the Langstroth hive. These he sold at two dollars each, if sold singly; but he said if they would take five they could have them for eight dollars. Their father advised them to purchase five, saying, if not all needed that year they would be needed some other year. With each hive he was to furnish a rack for holding section boxes.

After their return home their father directed them to clean out a small out-building, and use it as a storeroom for bee-fixtures, except things likely to be injured by rats or mice; such he advised them to place in the family storeroom where they would be safe. The children felt very proud of the nice new hives.

While all were absent at town that day, except Mrs. Meek, a man who made a business of cutting stencils for marking names on grain-sacks and the like, called at the parsonage to see if they wanted any thing of that kind. Mrs. Meek ordered from him a stencil for marking bee-hives, that would mark the name of the firm, "Jane Meek & Brother," in large letters; also a brush and bottle of marking-paint. When these were delivered, a few days afterward, and presented by her to the firm, Master Tommy indulged in quite a dance on one foot clapping his hands, and crying out, "Good! good!"

He and Jane soon had the name of the firm marked on the front of each cap. If Tommy had been permitted to have his way, it would have been marked all over the hives. The white hives, nicely painted with the name of the firm on the front of the caps in large black letters, looked finely. Mr. Meek had procured a price list of supplies kept by a dealer in a neighboring town, which he and the children had been looking over, and considering what they should order. At length the following order was made out and sent to the dealer: 500 sections, 5¼ inches by 6¼; one smoker; 50 tin separators to suit sections; 8 pounds of thin comb foundation, cut to fit sections.

All these arrived in due time, and were placed in the out-building, except the foundation, which was carefully laid away in the family storeroom. The neat sections, being all in one piece, with grooves for the corners, and the ends nicely dovetailed, were a marvel to the children, who immediately set to work to put them together. There were sections advertised of various sizes; but their reason for ordering that size was because the racks that came with the hives were made to fit that size.

In the spring they talked of having the bees transferred from the nail-keg into one of the new hives; but as Mr. Meek had never seen that work done, he advised them to let them alone, at least until after the swarming season. No honey-box was placed on the nail-keg, lest it might tend to delay the swarm. The whole family, but especially Jane and Tommy, were anxiously looking for the swarm to come off.

One day both Jane and Tommy rushed into their father's study, and hurried him away to look at the large bees flying around the hive. He pronounced them drones, and caught one or two for the children to examine, and see that they had no stings. He said it indicated that the bees were thinking of swarming. The children therefore watched the hive more closely.

One day the children were at work in the garden, when Tommy started to the house for the spade. He had to pass near the hive, and Jane was surprised to see him stop a moment and then begin a dance upon one foot, clapping his hands, and crying, "Good! good!" She called to him to know what was the matter, when he shouted at the top of his voice, "The bees are swarming! the bees are swarming!"

She soon stood by his side, and, sure enough, the bees were pouring out of the old keg in a perfect stream. As Tommy expressed it, they were tumbling out, heels over head. Jane thought of the new hives, and said, as she started for the out-house, "A hive! a hive!" and before their father or mother reached the yard they were back with the hive.

The children had never seen bees swarming before, and became greatly excited as they gazed upon the thousands of bees circling through the air. When they began to cluster on the low limb of an evergreen, Tommy seemed to lose all the sense he ever possessed; he danced first on one foot, then on the other, clapped his hands and threw his hat high into the air. He evidently hardly knew whether he was on foot or on horseback.

Their father said he would hive this swarm, to show them how to do it. He took a large cloth, and spread it on the ground beneath the tree. At one edge of it he placed the hive, the portico resting upon the cloth. He said they could be hived without the cloth, but he considered it a help. As the bees marched along over it to the hive they would not be hindered by the grass or weeds; and also by raising the edges, the bees could be shaken toward the hive if they marched too slowly. He then opened the hive to see that all was right inside, and that the boards above the frames were so fixed that no bees could enter the cap. He then asked for the dish-pan, which Jane brought. This he held beneath the cluster, while Jane and Tommy shook the limb vigorously, causing all the bees to drop into the pan. These he emptied on the cloth before the entrance of the new hive, and, breaking a twig from a tree, guided them as they marched in. The children came up close, and eagerly watched the proceedings. Fortunately their father caught sight of the queen as they marched in, and pointed her out to the children, who obtained a good view of her. Jane asked if she might take her up in her hands, and look at her more closely. Her father said, "No. A queen at this season is very precious, and; being full of eggs, is easily injured; and as you do not understand how to handle her without hurting her you had better let her alone."

By this time quite a bunch of bees had collected on the branch where the swarm had clustered. Mr. Meek had Jane hold the pan while Tommy shook down the bees, which she then emptied before the hive, as her father had done with the other panful. When these had entered, the hive was removed to the place where it was to stand. Mr. Meek elevated the back end of the hive, making it condsiderably higher than the front. When the children asked why he did so, he replied that M. Quinby's book tells us that if our young swarms are so placed, the bees will be more likely to build straight combs in the frames than if placed level; "and," said he, "we want straight combs."

Strange to say, that amidst all this excitement and flying of bees, not one person was stung, yet none wore any protection. Mr. Meek said the children ought to have some kind of protection for their faces, and explained to Jane how she could make one out of any old hat, by sewing a curtain to its rim with a piece of wire net in front, through which to see. To keep the bees from crawling under the curtain, it could either be tied around the neck or else have a jacket buttoned over it. She said she would make such a bee-hat for both herself and Tommy that afternoon.

To be continued June 1.

THE SOLAR WAX-EXTRACTOR.

FRIEND GREEN MAKES A CORRECTION.

YOUR cut of the solar wax-extractor is entitled, "Solar wax-extractor as devised by friend Green." I object. If you will examine the one I sent you, you will see that the cake of wax can be easily taken out of the wax-pan, as all of the sides are sloping, and there are no projections. With a square pan having projections inside, such as you illustrate, the cake of wax would have to be broken to get it out. Moreover, a part of the comb to be melted will be shaded by the straight sides of the pan, which will prevent satisfactory work. Of course, this could be prevented by keeping the comb away from the outer edges of the tray. I am inclined to think that the difference in results between the extractor I sent you and yours with only one thickness of glass was due to the unusual thickness of the glass I used, it being twice the ordinary thickness. **J. A. GREEN.**

Dayton, Ill., April 8, 1886.

Thank you, friend Green, for calling our attention to this matter. By some means or other the dripping-pan was made with perpendicular sides. We have notified the foreman of the tin-room, and the dripping-pan will hereafter be made with sloping sides.

LOCATION OF AN APIARY.

FRIEND FRANCE CONSIDERS THE VERY GREAT IMPORTANCE OF THE MATTER, BACKED BY LARGE EXPERIENCE.

AS I have had a great many questions sent me, I will try to answer them. In the location of an apiary, I am satisfied that a great deal of our success or ill success comes. I have had a good deal of experience in that line. I can count up ten locations in our neighborhood where we have kept bees within the last 15 years, which we have abandoned, and we are now using six locations. Why did we move? We got one location too near a public road; travelers and horses got stung; that won't do. The want of a good windbreak in other locations has caused us to move, and we are again to move one yard this spring, for the reason that the timber is nearly all cut away, which formerly has been our windbreak. The place is on a dividing ridge, and will not do without a good windbreak. My home apiary is on high ground. when I came on the place there was plenty of good timber all around me; but it is all cut off, and we have put up a tight board fence eight feet high on the east, north, and west sides. This does very well, but it is not so good as high timber.

We have one apiary 4½ miles N. E. of us that just suits me. The location is in a valley, between two ridges about one-fourth of a mile from the top of one ridge to the top of the other. On the north ridge, and nearly down to the valley, is thick timber—timber on the west, timber on the northeast, open to the south and southeast. The bees are placed close up to the timber on the north and west; for pasture they have an abundance of white clover all around them, with basswood two miles away.

In the year 1884, that yard, 41 colonies, spring count, and 72 fall count, gave us 130½ lbs. surplus on an average. In the spring of 1885 we had 70 good strong colonies in that yard, having lost only 2 out of the 72, one of which was queenless, and died early in the winter. The other was the last colony we made, which failed to mature their first queen, and had to raise another; so they went into the winter weak—about one quart of old bees. They lived until spring, and then dwindled away.

Another yard of 74 colonies, fall count, went down to 54—a loss of 20 colonies. Location had a great deal to do in making the difference in wintering those two yards. The last-named yard was in a valley very much like the other, as far as the make-up of the ground goes; but the apiary was on the north side, near the top of the ridge, with no windbreak on the north. There was timber on the east, close to the bees, and timber south near to the bees. A house and big barn and some timber were on the west, with a few trees among the bees. Now, had this yard been open to the east and south, and had there been a good windbreak north of them, they would have been all right; but as it was, there was too much shade, which kept the hives too damp and cold in the spring. The bees would come out, become chilled, and dwindle badly. We moved this apiary last June four miles to a better-protected location.

I am sure we can make bee-keeping a success, and winter our bees outdoors on their summer stands in this part of Wisconsin. If a man is going to commence bee-keeping, the first thing is pasture for his bees, and here the main dependence is white clover and basswood. Then if he is going to winter outdoors he must have good windbreaks—timber or high bluffs on the north and west sides. Locate the apiary on the north side of a valley, facing the south, and do not have shade-trees in the apiary. They keep the hives too moist. Give the apiary the benefit of the morning sun, to dry off the dew and warm them up. Look out for an easy way to get out of the apiary with the honey. Don't put the bees too near the dwelling-house or barn or stock-yard, nor near a public road, nor where the bees will be liable to sting folks about their work, or when traveling along the road. Don't locate with a meddlesome family, nor among them. It will cause no end of trouble and vexation. Locate with a good respectable family, and pay them well for their trouble. Keep on hand a few extra clean veils for the use of visitors; and when they come, treat them with due attention, and answer all their questions carefully. Don't be afraid you will teach somebody something.

DO WE OWN THE LAND WHERE OUR APIARIES ARE AWAY FROM HOME?

No. All the land we own is where we live and keep our home apiary. Other places we pay rent for, and we pay from $10.00 to $15.00 a year for each yard. We aim to pay about 25 to 30 cents a colony, spring count. We have never paid over 30, and we have no trouble in getting places at this price. The family have nothing to do with the bees. We do all the work; we visit each yard in the honey season once a week or ten days. If we attend to them in just a week, with no longer intervals, there will be no swarms out. We keep the queens' wings clipped, so in case they do swarm when we are away there are no swarms lost. The bees go back, and usually the queen gets back also. But in case the queen should be lost the last of June or first of July, or in any part of July for that matter, it is no loss at all as far as the honey crop is concerned. We never get any surplus honey after the 22d of July. Two years we have ceased our work on the 12th of July. Now, if we should lose a queen, say the 25th of June, her eggs keep on hatching until about the 15th of July. Those last-hatched bees won't get out to gather any honey until the harvest is over. I think we could get more honey with the queens taken away the 25th to the 30th of June than we could to have them remain, because then there would be an interval, right in the height of the honey-harvest, when there would not be a herd of hungry larvæ to feed. The bees will raise a young queen, so we shall have a young queen in the place of an old one to winter, and the young queen has plenty of time to raise bees to winter. The bees will work just as well without a queen as they will with one, providing they have material out of which to raise one. If I had a colony of bees that had the swarming fever, I would take away their queen, and that would cure them at once. But, of course, we should have to attend to cutting out queen-cells after that.

I think I have now answered all the questions I have on hand. E. FRANCE.

Plateville, Wis., Mar. 27, 1886.

Friend F., we are very much obliged indeed for the very valuable facts you give us. Within a mile of where I am now writing is a deep gully, surrounded on the north and west by hills covered with tall forest-trees. In this gully is a flat spot and a beautiful little spring; and for years I have wanted to locate an apiary just on that spot. As it is, however, half a mile from any wagon-road there would be some difficulty in getting to and from it. But your experience corroborates what I have long felt—that it would pay us well to select such spots for our bee-hives. On bleak cold days, when icicles are hanging everywhere, we find a pleasant summer temperature in protected nooks like these. Another trouble with my pet location is, there is not a house within half a mile. I have been thinking I should like to move some bees there and camp out during clover and linden bloom, and I really believe it would pay.

DETERMINATION OF SEX IN BEES.

AN INTERESTING CASE SHOWING THAT THE SIZE OF THE CELL PLAYS NO PART IN THE MATTER.

HAVING read with interest several articles in GLEANINGS on the subject of sex of the bee as determined by the queen, I will add an item which seems to me of some interest as bearing on the question.

Last summer I had a colony of blacks that became queenless. A comb of brood, with several queen cells, was given. These were soon all destroyed except two, and one of these was open at the side; but the larva appeared uninjured. I pressed the opening together closely, returned the frame, and smoked the bees *freely*. No further effort was made to destroy the cells. They were not again looked to till the young queen had been laying for several days. I then found part of one comb filled with drone-larvæ, as afterward proved to be the case. These, apparently, she produced first. I also found about two frames filled with worker-eggs, evidently laid afterward. These last were all in good shape, except that very few were in the center of bottom, but on the side of the cell, or near the side and on the base of the cell. The queen was looked up, and was found to be deformed. What seemed to be a scar, when seen under a magnifying power of four or five diameters, was found upon the upper right-hand surface of the abdomen, beginning in the first ring, and extending backward and slightly forward across the second and third rings, and terminating near the middle of the fourth in a sort of knotty appearance, and with a slight protuberance. The extremity of the abdomen was drawn to the right so much as to be nearly on a line with the right side of the abdomen. The whole of the abdomen had the appearance of being stretched in length, but was very small, no part being larger than a good-sized oat straw, seemingly because the injury, or whatever it was, caused the mark, or scar, described. This queen produced worker-eggs and also a few drones in the few drone-cells to be found in the hive, putting each in its proper place, except the drones at first, though it was impossible that the abdomen should be compressed by the cell, or even touched at the same time by the opposite sides of the smallest worker-cell.

Now, I do not *know* that this queen came from the injured cell, but I believe she did, and that the mark described was caused by the torn edge of the cell pressed in upon the larva by my unskillful attempt to repair the cell, which, while not rupturing the skin of the larva, did, by pressure, while the larva was in process of development, cause the scar described. This queen produced both drone and worker eggs, according to the cell being occupied (except at first as stated above), and that without any pressure of the cell in any case, the diameter of the abdomen not exceeding two-thirds that of the smallest cell. Now, if this queen could produce fertile eggs without the much-talked-of pressure of cell, is not the conclusion natural and reasonable that others or all can also? My own experiments and observation have satisfied me that drones may be, and, in *rare cases*, are, produced from worker-eggs; but that it is unusual, and possible only when done almost immediately after the deposit of the egg by the queen. 8—L. T. AYERS—120.

Farina, Fayette Co., Ill.

Friend A., you have given us a valuable fact. I have several times patched up queen-cells when they were torn open, and had them hatch out good queens. Sometimes the queens will hatch out all right, without being patched up, if the bees take a notion to let them remain that way. It is quite common for young queens to produce only drone-eggs at first, and worker-eggs in proper order afterward.

HOW TO CREATE A MARKET FOR HONEY.

SHALL WE ADVERTISE AS DO PATENT-MEDICINE MEN?

THE great cry of honey-producers is, "Sell all that you can at home before shipping to the large markets;" but, now, what shall we do to start this home market? Some say, "Advertise liberally in your local papers;" but what is the use of advertising an article that the people do not know that they want or need? Some say, "Write up pieces, and have them inserted in your home papers;" but you take the honey-producers through the country and how many could you find who would or could write any thing that would have any weight with the public? Then what can we do to educate the people, and counteract such lies as Wiley's or Wells'? There are but few whom we can reach individually; and then, unless they are personal acquaintances, or know your reputation well enough to believe you, you could not convince them that you had a genuine article unless you could out-talk all the book-agents and lightning-rod peddlers in the country; and who can blame them when, a short time ago, they could hardly pick up a paper but had something in it about adulterated honey, or something as absurd?

Now, is there not some way that we can educate them to the use of honey? Can we not copy after the patent-medicine men, and keep honey before the public all the time? I find that the most of the papers throughout the country are using short stereotyped pieces to fill out their papers, especially when they have job work which pays them better, and that they would gladly use any such thing as would interest and instruct their readers. Then why can't we have such pieces? And, friend Root, I think you are just the one to get them up for us. You could offer prizes for short essays on honey, print them in GLEANINGS, stereotype, and have them ready to scatter broadcast through the country; and, as nearly as I can learn, the price of two or three pounds of honey would give a short piece each week for the people to think about; and if it seemed to have no object but to fill up the papers, they would have more confidence in it than any advertisement that you could get up; and then with a short local, telling them where they could get it, and by having it in a neat and attractive form at the leading groceries, it could be made a financial success to all parties. What we want is short pieces to make honey-consumers, not honey-producers. Let us hear from you, so that we can work up this or some better plan to help us dispose of the coming harvest that we hope to receive.

Bangor, Mich., April 9, 1886. J. J. PENOYER.

No doubt, friend P., much could be done to help the sale of honey in the way you propose, and considerable is being done in that way. In reading our agricultural exchanges, I have been pleased of late to note a considerable space being given to bee and honey interests, and I am glad to see the sensational stories about artificial eggs and artificial comb honey giving place to sound sense. One trouble about advertising honey to the extent that patent medicines are advertised is, that there is not profit enough in honey. There is often not a difference of two cents a pound between wholesale and retail; but with patent medicines, an article that costs only 20 or 25 cts. per bottle, every thing included, sells for from $1.00 to $1.50 per bottle. With such a margin, you see they can afford to fill the papers with flaming advertisements. It is very rare that staple food products afford any great margin.

FORCING BEES INTO SECTIONS.

J. E. POND'S METHOD.

ONE of the troubles existing in the matter of securing comb honey consists in the reluctance of the bees at times to occupy the sections early; the consequence of their not doing so, being excessive swarming. Many plans have been adopted to overcome this reluctance, and many theories have been urged as to its cause. None of them, in my opinion, have hit it just right as yet; at least, no one as yet succeeds to the extent that may be fairly called success. The exponents of the reversible plan have the floor at present in theory; in practice, however, this method is so cumbersome and unwieldy, whether frames are reversed singly or aggregately by reversing the hive, that it will hardly supersede the methods most commonly in vogue. For the last two or three years I have been experimenting somewhat in this direction with results that so far are quite satisfactory to myself, both in the results attained and the labor involved. It is a well-known fact, that bees deposit their surplus most largely above the brood, and the natural reason for this is at once apparent. It is a well-known fact, too, that store combs are always (when room is given) built deeper than those used for brood, and equally true that brood is not reared in combs that are more than ⅞ inch wide. The logical deduction from all this is, that when the frames are spaced at such a width apart that the comb can be built out to a greater than the regular width such combs will be used for storage, and, as a consequence, the sections will not be occupied for that purpose, while any room therefore remains in the brood-chamber. It also follows, that if the comb is spaced only a bee-space apart, it will not likely be used for storage, but will be used for brood. These propositions were so self-evidently true to myself, that I have given the matter a fair test during the last three years, and these predicated results followed in every instance.

I tried reversing-combs; and while I found them fairly successful, I also found that it required too much time and labor, and that closer watching was required than I was able to give. I then adopted the plan of forcing each colony to full size as early as possible; and on the near approach of the honey season I extracted the combs in brood-chamber and shaved them down to exactly ⅞ inch in width; then I replaced the frames in the brood-chamber just a bee-space apart, using dummies with which to fill empty space. By this plan I have found the brood-chamber was used for brood alone in the early season, and that the bees would occupy the sections as soon as they were placed upon the frames; this I found, also, was a labor-saving operation, and a great saving in time also. I am aware that the theory of the reversionists is, that all surplus should be forced into sections, and the winter stores supplied by feeding. This is theory to a great extent, and as yet requires verification by actual tests, not by one or two in their own localities, but by the masses generally throughout the whole country. With my method, by removing a frame or two at the close of the honey season, and widening the spaces between those remaining, the same state of things will, of course, result. The method above indicated is not only practicable and practical theoretically, but has been tested, as I have indicated, to an extent sufficient to positively assure me that it is worthy of being tested on a large scale. I do not advise any great or expensive changes, and in order to try this plan none such are required; for while I myself use the L. hive, my method can be used with any other that contains frames ⅞ inch wide, and no expense whatever need be made in adopting it. Whether or not this method may be deemed practicable by others, I am so well pleased with it that I shall continue its use in working for comb honey, knowing that equally good results can be obtained by so doing as by reversing either frames or hives, and with less trouble and expense.

Foxboro, Mass., April, 1886. J. E. Pond, Jr.

Friend P., while your plan may not have been followed up exactly as you have it, it has been touched upon from time to time during past years. Where you move the combs up to only a bee-space apart, it is necessary that they should be very flat and straight, or bees will be imprisoned in their cells, or the cells will be closed up so that even the nurse-bees have no access. On this account I would keep the combs occupying the same relative places to each other as much as possible when working in that way.

BEES IN TEXAS

That Build Their Nests to Limbs of Trees, in the Form of a Sphere.

DO BLACKS AND HYBRIDS EVER BUILD THEIR COMBS TO LIMBS OF TREES LIKE A HORNET'S NEST?

ON page 829, Dec. 1, 1885, Mr. McCamant recites an incident related by Rev. F. B. Ticknor, of finding in Western Texas a colony of bees styled "Mexican bees." Had the Rev. Mr. Ticknor carefully investigated those bees, I think he would have found them to have been only common blacks or hybrids, or stray Italian bees. I found a colony of common black bees last year, clustered on the end of a broken limb, about 30 feet high. The comb, as Mr. T. says, was somewhat shaped, or resembles, a hornet's nest. First a central straight comb about 14 inches long by 12 wide under the limb, which was about two inches in diameter; two others, one on either side, about 12 long by 10 inches wide, attached to the limb, arching outward, and held in position by a comb-brace about 3½ inches long by 1½ thick, the cell walls being fully four times as thick as the ordinary comb-cells were; the partition wall of this comb-brace was about ⅛ inch thick. Then on either side were two more pairs of arched combs with braces as above described, the first pair being about 9 inches long by 8 wide; the last pair was about 6½ inches long by 4 wide. They were all arched over and attached to their fellows nearly their whole length. The free edges indicated that they had been started at the comb-brace, and had been arched over for additional support. There were no cells on the arched part of the combs above until they became about vertical, and then but very shallow cells on the outside of the two smaller combs. Under the arch, however, the cells were complete over the entire combs. The brood-nest was below the comb-brace, and occupied most of the lower part of the three central combs. The inside of the fourth and fifth combs, except about an inch at the bottom of all the combs, was filled with honey, the combs all tapered to a thin edge at the bottom and the free extremities. The whole mass could very easily be imagined to resemble a hornet's nest.

Did the bees reason, so to speak, that the arching combs would protect the brood and cluster from rain? or did they arch the combs over to get additional support? I think the latter at least the main reason for arching over. I have seen bees clustered, and combs built on limbs, in Indiana; but I never saw such swarms build combs in a globular form there. There is nothing in the above but what obtains where bees build natural combs in a hive, except the arching and comb-braces. The comb-brace was evidently built heavy to prevent the comb from encroaching on its fellow, and was necessary as a starter for the next comb. The globular form of the comb might lead to the belief of a distinct race of bees; aside from that, I see nothing to warrant such an opinion, and I think investigation will prove my conclusion correct; i. e., they are blacks or hybrids. I should be proud to believe America to be the home of a race of bees *better than the best;* but if such is to be the case, it will be by selecting from the best of other lands, and rendering them homogeneous, and so raising up a Saul in Israel, or a strain, head and shoulders above all others. E. S. ARWINE.

Patterson, Texas.

MORE FACTS TO SHOW THAT BEES NEED SALT.

BEES CONTROLLING THE SEX OF THE EGG.

ON page 178 I saw an article from W. H. Green, entitled, "Salt a Necessary Element for Bees." His experience only relates what is an *absolute* fact, that salt is one thing necessary in making up the food of the bees. If any one has not tried it he will be surprised to see how eager they are for salt, when put in proper shape for them to get at it handy. While keeping bees in California, where there was plenty of foul brood all around us, I used to prepare all the drinking-water my bees used, and the water was medicated with salt, salicylic acid, and borax, but it was made pretty salt. I gave it to them in shallow dishes, with a loose piece of sack thrown over it. The sack was allowed to fall down in the center, leaving the edges hanging over the dish. The bees would suck the water through the sack, and take every drop of the medicated water from the dish. This water was given to them every morning, as regular as the morning came. I used it as a preventive of foul brood. I took the ground that the salt and salicylic acid were both disinfectants; and as the bees fed the young larvæ the water I prepared, it must of necessity benefit them; that is, if there were any germs of foul brood in the combs.

Now, friend Root, I have been much interested in the articles of Chas. Dadant and Prof. Cook on "Egg-laying of Queens." While I have no disposition to open a controversy with two such able correspondents as the above, yet they will allow me to say that I think there is much to learn about the egg-laying of queens. Under some circumstances their ways are past finding out. Now, what old observing bee-keeper has not seen queens, drones, and workers, all reared from what we *suppose* to be the same eggs? Take a full sheet of worker-comb (not a cell of drone-comb in it) from a prosperous colony, before the eggs are hatched, and place it in a queenless colony that has no brood of any kind and sometimes they will rear queens, drones, and workers from this sheet of eggs, that, had it been left in the parent colony, would in all probability have been every one worker-bees. I have had them cut down the worker-cells to the septum, build drone-cells, and rear as fine-looking drones as I ever saw reared under any circumstances. Can you tell how they manage it? I give it up, and am willing to let some one else try. Will Prof. Cook or Mr. Dadant give his views? It is light that I am after, not criticism. For the sake of courtesy, I might wish that I could agree with either of the gentlemen's views upon the subject; but my observation has led me to the belief that, in the instance where young queens lay drone-eggs before they begin laying worker-eggs, is because they had not yet met the drone; and if I say that I am inclined to say as you do, that the bees have the power to determine the sex, I shall not be accused of departing from the ground I have taken before. A. W. OSBURN.

Havana, Cuba, March 15, 1886.

This subject as to whether the bees can convert worker-eggs into drones has been discussed a good deal already. At the convention at Detroit last fall it came up, and some of our wisest heads discussed it; but as a rule I think they seemed to be a good deal incredulous. It seems to me as though brood that would have ordinarily produced worker-brood is often converted into drone-brood when put into a queenless hive. We want careful experiments in the matter.

MOVING BEES IN MID-WINTER.

WINTERED WITHOUT LOSS.

THERE is no doubt but that perfect quiet is the best, when once the colony has compactly custered, and winter has set in in earnest. But circumstances *may* be such, sometimes, that some unforeseen emergency may occur when we are almost compelled to handle a colony in mid-winter. Then the query naturally comes up, Can we do so without endangering the life of the swarm? I have tested this matter more thoroughly the past winter than I ever did before. I had purchased 7 colonies long after my own had been snugly packed away in the cellar. He had left them out on their summer stands, without any extra packing or care. On the 13th of Jan., when the thermometer was 10° above zero, I took a sled and went twelve miles after the bees, in a very deep snow. This was only four days after the noted four-days' blizzard, during which time the thermometer had been, much of the time, down to 15° and 20° below zero. Of course the bees became very much aroused by the time I got home, and it was with much misgiving that I set them in the cellar. I watched them closely at intervals during the remainder of the winter, and was pleased to see that, in a day or two, they had settled down to that peaceful quiescent state, so satisfactory to the apiarist. Two days ago they were put on their summer stands, and all came out bright and dry, and strong in bees and stores.

My 61 colonies were set in a house-cellar the 5th of Dec., and the 7 colonies were set in the 13th of Jan., as before mentioned. They *all* came out, not only *alive*, but bright and clean, with only half a dozen or so with entrances a little specked up with dysentery. They have been busily engaged bringing in pollen and some honey from soft maple.

Our cellar is quite dry, and well banked up with slough hay. They had no ventilation, or, rather, the cellar had no ventilation, except what was afforded from passing in and out once or twice a day form an outside door. The bees were tiered up four deep, as compactly as possible, with full-width entrances open, and each cover slipped forward, so as to let the bees pass in and out at will, at each end of the top of the hives—no quilt, no chaff, or absorbents of any kind. I hung a good thermometer over the hives, and kept the temperature at 45° to 50° all winter, by firing pretty heavily during very cold weather, in a sitting-room over the bees. We kept potatoes, apples, milk, canned fruit, etc., in the cellar; and, worst of all, about 100 rats, more or less, took up their abode in the cellar. But I soon fixed them with poison.

You ask if I advocate this kind of cellar for bees. No: I have a model bee-cave in construction (mentally) with circular cement brick for arching overhead, and with tile sub-earth ventilators, etc.; and so confident do I feel of successful wintering, provided they have feed late, and have good stores, that I would not wish to give any great sum to have them insured to winter over. D. E. **Brubaker.**

Maxwell, Story Co., Ia., Apr. 9, 1886.

Friend B., although you wintered your bees safely that were moved during a low temperature, I do not think it would be safe to say that we can do it as a rule. In our back volumes, several cases have been noted where bees undisturbed wintered nicely, while those moved in the middle of the winter, in much the same way you moved yours, all died with the dysentery, showing conclusively, it would seem, that disturbance was the cause of the mortality. There is something very complex and perplexing in this whole matter of wintering bees, and the results of the experiments are so very conflicting that it is a very difficult matter indeed to decide *positively* on any thing.

AN A B C SCHOLAR'S SUCCESS.

WINTERING WITH PROTECTED, CONTRASTED WITH UNPROTECTED HIVES.

IN the fall of 1884, Frank S. Ledyard, who has been one of your patrons, sold off all his bees at a public sale. As we had been without bees for several years, I concluded to purchase one colony and try *my* hand as a bee-man. I therefore bought his best swarm, which were pure Italians, paying him $7.00 for it. Father also bought a weaker swarm for $4.00. Mr. L. also had a very weak colony which he did not sell. I got him to put our three colonies into winter quarters, which he did by placing a rough box around each hive, leaving a space of about six inches, to be filled with dry planer-shavings. An empty hive was also placed upon the lower story, which was also nearly filled with shavings. After placing the lid on top, and a roof over all, they were ready for the winter. Now, everybody who knows any thing about bees, and the winter of 1884-'5, knows that it was a "stunner" for bees. This section of country never had such a mortality in the apiaries. One of my nearest neighbors, Mr. R. B. Robbins, who has also been one of your contributors and patrons, lost his entire stock, and *he* claimed to have a *hardy* strain of bees. Well, when spring came, father discovered that his swarm must be interred in the same graveyard as the *hardy* strain, while Mr. L.'s and mine remained to gather the honey.

About this time I received a copy of the A B C book, and began reading it carefully. My swarm came out very strong and bright in the spring. On the fourth of June I took out one card of brood and formed a nucleus for father, and made two starters of the remainder, each having four cards of brood and comb. I added empty combs to each as was needed, until each was full again. The one that had the queen, built up very fast, while the other was more backward. I soon discovered that they were rearing queens, and in a short time had 17 cells nicely capped. Just before they hatched out I removed all but one or two, and placed some in wire cages on top of the frames to hatch out, which they did very nicely, and were fed by the bees from below. In about two weeks from the time I divided the swarm, I took two cards of brood from the colony having the queen, adding several empty combs, and placed them in a hive where the old colony stood, moving the former a little to one side. I also gave them a virgin queen. It was surprising to see how fast the young colony built up. The old hive was nearly destitute of its workers for a few days, while the young hive was just booming. In five days they threw out a swarm which returned; the next day they did the same thing. I couldn't think what was the matter. When they came out the third time my brother hived them and gave them one of my caged virgin queens, which they at once accepted and settled down to business. I afterward concluded that the reason they persisted so in swarming was because they were too much crowded, as I had placed division-boards in the hive, having only five combs. Do you think I was right?

The nucleus that I formed for father rapidly became a strong colony, and in the latter part of July I took several cards of brood from it and formed another for him, which made rather slow progress during the season.

The season for honey in this locality was just moderate. The white clover honey was only a medium yield, but a very fine quality. The basswood was unusually full of bloom. I heard men of experience say that the flow at no time was very heavy, but the bloom continued much longer than usual, so that an average yield was received. My bees obtained quite a supply from the buckwheat, but the greater part was obtained from the white-clover and basswood.

Last fall I went into winter quarters with six colonies of my own, father having two. I packed them the same as the previous winter. Besides giving them all plenty of honey for winter stores, I obtained about 30 lbs. of comb, and 50 lbs. of extracted honey, which commanded a price of 10 and 15 cents per lb. M. B. **Simon.**

Bloomdale, Ohio.

COREOPSIS HONEY.

THE FLORA OF FARINA, ILL.

THERE are some peculiarities respecting the honey resources in this locality that might interest the readers of Gleanings. I have been keeping bees for the past 16 years in this place, and have yet to see the first pound of surplus honey gathered from clover or basswood in this locality. Until the summer of 1882, I usually had to feed my bees in June to prevent their starving. By the first week in July they would usually become self-supporting, getting honey enough to live on, from plants of the mint family principally.

After the great drought of 1881, which killed out much of the grass in road-sides and pastures white clover (which had not been hindered from perfecting its seed) came in quite strong, but yet not enough for any surplus, nor enough to induce much swarming. Near the timber, bees get plum and crabapple and other forest bloom, and build up strong earlier than on the prairie. But that is not very important, unless one wishes to sell bees by the pound, since we rarely get any surplus before August, unless honey-dew puts in an appearance, which it sometimes does in June. Early in August the bees usually begin to get a little surplus. By the middle of the month they are frequently getting a fair yield from some of the larger species of the smartweed family.

Our main dependence, however, is *Coreopsis Aristosa*, usually, though erroneously, called Spanish needle. It begins to secrete nectar about the 27th of Aug., and lasts 15 to 17 days. It grows on dry land as well as wet. Many of the stubble-fields appear like a solid mass of yellow bloom. There are usually some hundreds of acres of coreopsis bloom within range of my bees.

About the only causes for failure to get a good yield of honey from coreopsis are, either a severe drought, or weather so cool as to prevent the bees from working. During the past 16 years we have not had a single season in which our bees failed to get abundant winter stores, though we have had two seasons in which they failed to get any surplus to speak of. Once the failure was due to cold weather which prevailed during the coreopsis bloom, in the year 1879. The second failure was during the severe drought of 1881. We have had other seasons when the yield was materially diminished by very cool or very dry weather. In fact, I believe our honey-crop this year was shortened one-half by the cold weather that prevailed in August and September.

The honey gathered from coreopsis is thick, weighing 12 lbs. to the gallon. It has a beautiful amber color, has a pleasant aromatic flavor, and does not leave any rank or unpleasant taste in the mouth. I have never known it to become sour, or foam up, as some other grades often do when extracted too soon. It is very slow to granulate, usually remaining liquid until near the close of winter. Its thick and non-souring qualities make it a good winter feed for bees. My winter losses have been light, though kept on their summer stands, last winter being my poorest record, with a loss of only ten per cent. Bees do not build comb or draw out foundation as readily when gathering this thick coreopsis honey as when working on the thinner smartweed or clover honey. Bees show very little desire to swarm while working upon it; and since our honey-supply before that is usually too scanty to induce swarming, we get along with very little natural increase. In fact, during the past two years, without trying to repress swarming, I don't think I have had more than six natural swarms, and yet my honey-crop for that time has amounted to 18,000 lbs. This coreopsis, while so plentiful here, seems to abound only in limited areas.

To make this a good honey locality, we need clover in addition to our present resources. I think this want can be best met by cultivating alsike clover in our meadows and pastures.

16—T. P. ANDREWS, 245.

Farina, Fayette Co., Ill., Dec., 1885.

We have had quite a quantity of the honey mentioned above, but we always called it goldenrod honey. During a conversation with friend Andrews at New Orleans, I became convinced that what we call goldenrod honey is honey from the Spanish needle. The body and flavor are excellent; and when it is so thick that a saucerful may be turned over without spilling, it candies little or none at all. Its dark amber color seems to be the worst thing against it; but when it is better known and recognized, it seems to me the price ought to rank nearly if not quite equal to that of the best clover or basswood honey.

A LETTER FROM THE ISLAND OF CYPRUS.

GETTING SWARMS TO CLUSTER ON THE SAME SPOT DURING THE SEASON.

THE goods you forwarded to me arrived in good condition. I am glad to say that every thing was found nice; the foundation machine works beautifully.

Having derived much benefit from reports I read in GLEANINGS, I consider it is my duty to report a discovery I made in bringing down swarms during last season.

I started bee-keeping with ten stocks in February last. In May I had twelve swarms; before the swarming commenced I was told by a lady that swarms prefer clustering on orange or lemon trees to any other kind of tree. As I have only two of this kind of trees in my house, and as they are far in the other corner of the garden, I thought I could use the small branches and shoots thereof by cutting and hanging them on the branches of the pomegranate-trees which are near to the hives.

On the day I was expecting the first swarm I cut two shoots from the lemon-tree, each having about ten leaves; and having first rubbed the leaves to make the smell rise, I tied them on the pomegranate-tree, which was about four yards distant from the hive. About three hours after, the expected swarm came out and went right on the said lemon leaves; and after all the swarming bees were settled thereon, I slowly removed the cluster into a hive.

Some days after, I saw another hive was swarming. I immediately cut off a small branch of lemon-tree; while I was tying it on a tree, my servant brought to me another branch from the orange-tree, the leaves of which I rubbed, and secured it to the same tree, but about one yard from the former; then the half of the bees clustered on the lemon leaves and the other half on the orange-leaves, making two separate clusters of one swarm. I hived them separately in nucleus hives on combs, one partly filled with honey and pollen, the other empty. The bees from the one having the empty combs went to their parent hive because there was no queen with them. Three other swarms I caused to cluster on the lemon branches while I was holding them up for the bees. At the time when the other swarms were seen in the air, in my absence from the house, my servant caused them to go straight into the hives prepared for them, having thrown into the hives a few leaves of a lemon-tree.

I am sure I lost no swarm, and I hope I shall not lose any so long as I shall use such a bee-magnet. I think that orange-water, or lavender, used for toilet, will attract swarms to any place desired, the same as fresh leaves of orange or lemon trees do.

M. S. DERVISHIAN.

Larnaca, Cyprus, Feb. 5, 1886.

Thank you, friend D., for your kind report from your far-away apiary. In regard to the efficacy of orange or lemon trees, it may be that the peculiar scent of the leaves is attractive to the bees, in the same way in which the scent of the oil of anise seems to attract wild bees in bee-hunting. But after you have once succeeded in getting a swarm to cluster on one particular limb or branch, there is nothing particularly new in the fact that all subsequent swarms cluster on the same branch. The matter has often been discussed in our back volumes. It is quite common to have almost every swarm from an apiary cluster on the same spot, or on the same limb, that the first swarm of the season occupied. Especially is this the case after two or more have occupied the same tree or branch.

UPWARD VENTILATION.

EVERY RULE HAS ITS EXCEPTIONS IN BEE CULTURE.

FRIEND G. M. Doolittle, on page 266, argues against the necessity of confining the heat of bees to the hive by contracting the hive and restricting upward ventilation. Whether he does this simply for argument or not, I do not know; but as I have been a supporter of the opposition, and you have alluded to me as such, I wish to say a few more words on the subject.

Every rule has its exceptions, and there are but few rules in bee-keeping which may not be disregarded with impunity under certain conditions. Experience has convinced me that bees, to winter well under ordinary and average conditions, should be restricted to a small hive, well protected from the cold, and as nearly air-tight as possible, except at the entrance, which should be large. Do not understand me to say that bees will not winter well under other conditions. Some of the most successfully wintered colonies I have ever had were wintered in large hives with free upward ventilation. In my spring report, given on page 382 of July GLEANINGS for 1883, are these words: "One of the strongest swarms I have was wintered in a large chaff hive, with 12 frames below and 5 above, only partially covered with a piece of duck."

As I look back over the many experiments I have made in this line, and think of what I have learned from others, I can recall cases where colonies that have wintered well in large hives, with an abundance of ventilation, seemed to show an unusual degree of vigor and energy the next season. Whether this energy is the cause or result of their successful wintering, I do not know; but I am inclined to think it is the former. I have often thought it was because colonies in large hives are not apt to be subjected to the overhauling and disturbance of the brood-nest that is likely to fall to the lot of those in contracted hives.

I am not simply arguing in support of a theory, suppressing all facts I know that may seem to disprove that theory. It is the truth that I am seeking, and, if I find it, I care not what theories are overthrown.

I freely admit, that I have frequently been successful in wintering in large hives, and with free upward ventilation; but the ratio of loss has been so much greater in the colonies wintered by this method that I have come to the conclusions given in my article on page 42 of the present volume.

Oliver Foster hits the nail squarely upon the head on page 256. We never hear that "upper absorbents" are necessary in ventilating our homes and public buildings. The impurities of the air must be removed by ventilation and not by absorption, and it is generally agreed that the most satisfactory and economical systems of ventilation are those which provide for the escape of the contaminated air at the bottom of the apartment. It is true, that the impurities thrown off into the air by the respiratory organs and the excretory organs of the skin rise at first; but becoming chilled, they fall to the bottom. Moisture is far from being the only thing added to air by an animal living in it. The same principles apply to a bee-hive. Bees can not go into that hibernating condition assumed by many other insects, wherein they can endure the most extreme cold of winter in a state of complete torpor, requiring no food to nourish them or sustain animal heat. The inmates of the bee-hive must at all times maintain a certain temperature, and they must consume food in order to do this. If the whole of a colony of bees should be chilled into that benumbed and torpid condition which the outside bees of the cluster fall into during cold weather, it is very probable that they would never revive unless they were warmed up very soon by a change in the weather.

The interior of the hive, and particularly the interior of the cluster, is much warmer than the outside temperature. This heat must be maintained by the consumption of honey. The colder the hive, the more honey must be consumed, and the more the vital forces of the bees are wasted in digesting this honey. Economy of heat is economy of vital force. Small hives, closely sealed above, are most economical of heat; therefore, other conditions being equal, they are best adapted to the outdoor wintering of bees. J. A. GREEN.

Dayton, Ill., April 8, 1886.

FLORIDA.

NOT A LAND DISAGREEABLY COLD IN WINTER OR EXTREMELY HOT IN SUMMER.

I HAVE often felt a desire to express some of my heart-felt gratitude for the many bits of good counsel coming from you through GLEANINGS, which comes to me very regularly, and is read with untiring interest and pleasure. I always feel edified and strengthened after reading your lectures, and my heart and mind run out to my neighbors who take GLEANINGS, and I feel so glad that they have the benefit, too, of so good a lesson, besides the many good practical ideas that come to me through it from yourself, Ernest, and other good bee-men and bee-women. This is a great organ, and is calculated to do a great deal of good. I am glad to say I have never seen any thing in GLEANINGS, except Jay C. Ell's letter, taken from the Charlottesville *Chronicle*, which contained any thing disparaging to Florida; and I was sorry to see such an envious, exaggerated statement in as pure a work as I have always felt GLEANINGS to be; and as dearly as I love the editor of it, I can't help but feel a little disappointed to see such an unjust and exaggerated statement; and it seems that Mr. Griffin showed some Levite spirit too in the matter.

Mr. E. is what the many respectable, well-to-do Northern settlers here term one of the black sheep, which is very natural and common, as there are some in every flock. Such sift themselves out of here. It requires vim and judgment to succeed here as well as in many other places; and it seems that Florida must be a God-forsaken land, instead of a land blest with flowers, where even the thermometers will not indicate truth, much less interested land-agents that do their work by writing and talking. I do not approve of exaggerating, as no doubt some of the many land-agents of Florida do, for there are some black ones among them.

I approve of Mr. W. S. Hart's advice to those contemplating moving to Florida—come and see before pulling up your stakes where you are, unless you know some man or friend who has an honest purpose at heart, and has sound judgment, such as you can trust to advise in so important a matter as moving into a new country and climate, especially where a man has a family. There are a great many things to look out for besides land-agents. As for society, I feel it my duty to say that it is good. We have churches of nearly or quite all denominations. They are well attended in most parts. Schools, I can not say are good, though improving very rapidly.

Again, Mr. E. not only asserts that thermometers are worthless, but that the climate is a fraud. I do not know how that is; but I feel sure that God never made nor ordered any frauds in his kingdom. Now, because we had a cold snap the past winter that spoiled our oranges and vegetables, and killed some small seedlings, we must not denounce God's ruling and shut our eyes to keep from seeing his blessings and wisdom. I haven't a doubt but that the cold here last winter was a blessing instead of a fraud, if we could see through God's wisdom in sending it. As much as has been said about the cold and hot weather in Florida, I feel inclined to state just here a little of my experience in the twelve years that I have been in the State. I am neither a Floridian nor a land-agent.

The lowest that the thermometer had been until this winter, at my place, was 28°. This winter it got down to 22°, the highest 95°. Just here I have to differ with Mr. E. again. I have never felt it uncomfortably cold to work out of doors, nor so oppressively hot the hottest day as it was up north, where I was raised. The nights are delightful, both winter and summer.

A word in explanation to those who are not familiar with our situation and the causes of our pleasant summers. We are between the Gulf of Mexico and the Atlantic Ocean, consequently we are fanned by the gentle breezes from one or the other, almost every day during summer. This breeze reaches us here in Orange Co. from 7 to 9 o'clock A. M.

Now a word about the precious little busy bees. I have 28 colonies, all Italianized, one Bellinzona and one Carniolan. They are all gathering honey, and rearing brood nicely. Some of them have drones out this 8th of March.

Pardon me, friend R., for one question just here. Will yellow-jessamine honey kill young bees? Some of them seem to sicken and die from the first sip they take after they come out. This disease does not affect the Carniolans. I hope to give a more favorable report of my bees later in the season. JOHN S. WOMBLE.

Oviedo, Fla., March 8, 1886.

Friend W., may be the report from the *Chronicle* was a little severe; but there are certainly extremes both ways, and no one would want people to sell out and go to Florida, to be disappointed after getting there. No doubt the cold snap in Florida will prove to be a blessing if taken right; but the same rule will apply north as well as south. The writer of the article alluded to meant to say that thermometers didn't seem to him to be worth as much as a guide, as here in the North. I am glad you like your Southern home.—I do not think that the honey from the yellow jessamine ever kills bees at all; and Prof. Cook takes the liberty of doubting whether it ever kills anybody, if eaten in moderation.

REPORTS ENCOURAGING.

GOOD REPORT FROM AN A B C SCHOLAR IN NEW ZEALAND.

IN the month of January, 1883, a vagrant swarm of bees thought proper to cluster on a small tree near our house. I got an empty candle-box, and so hived my first swarm of bees. A few days after, neighbor K. called and tried to impress upon me the advantages of the modern system of bee-keeping, and, by way of proving his arguments to be correct, he gave me a Simplicity hive and ten frames, with fdn. starters, and transferred my bees for me. He also lent me your A B C and a great pile of GLEANINGS. This interested me so much that I resolved to try to raise honey sufficient for our own use. At the end of the next season I had 8 colonies of bees and 150 lbs. of honey. Another year passed away, when I had 16 colonies and 1500 lbs. of honey; and now, Mar. 1, 1886, I have 27 colonies of bees and 3200 lbs. of extracted honey. During this time I have not bought any bees, and have tried to keep them from increasing too much.

It seems to me that the most important question for the apiarists of this country will be, how to prevent swarming, and how to sell honey. There is no trouble in wintering bees. They can be left in their Simplicity hives on the summer stands, with a cushion over the mat; and if they have plenty of honey there is no fear of loss. We have no snow here, except on very high mountains, and very little frost — what we call hoar frost, in the night, making the ground white, and forming thin ice in small puddles; but, when freezing at night, the days are always very fine and warm. The summer time is not so extremely hot as with you. We think 80° warm weather; 92° in the shade is the highest I have known, and that does not often occur; and even then, mount Ruapheu, which is about 60 miles distant, can be plainly seen, towering up in the sky, its summit covered with perpetual snow.

I think I may say that your Simplicity hive and frame is the standard national hive of this country. Of course, we have some men who regard an *alteration* as an *improvement;* but these are very few GLEANINGS just suits me; its mixed character adds greatly to its value, in my opinion. I have gained more information as to the climate, natural production, manners, and customs, of America and its people, from GLEANINGS, than, from all the histories and books of travel I have read. We have been in the habit of saying, "Our American *cousins!*" but the kind and friendly tone of GLEANINGS makes me feel like saying, "My American *brothers.*" We are of the same origin, with the same literature and language; and I hope the time will soon come when we shall unite in one great brotherhood, to turn the sword and spear into plowshares and pruning-hooks, and resolve that there shall be no more war, but peace. J. WOOD.

Ohaupo, Auckland, New Zealand, Mar. 1, 1886.

Well done, *brother* Wood. We thank you for the kind compliments you pay us, and we reiterate your words. Let us by all means strive to be brothers, even though the ocean may separate us.

FROM 5 LBS. OF BEES TO OVER 10 COLONIES; A KIND WORD, ALSO, FOR E. M. HAYHURST.

I am a dentist, not an apiarian; but nevertheless I may have some latent or undeveloped apiarian powers or qualifications; and, indeed, if enthusiasm and love for the bee and its habits, save its sting, are ear-marks of an apiarian, I have great hopes of success, for these attributes I possess in a marked degree. On May 17 last, I received of E. M. Hayhurst, through Mr. Harry Hobbs, 5 lbs. of bees and five queens. The order and the money sent was for *warranted* queens, and just see how badly (?) Mr. Hayhurst treated me. Owing to the lateness of the season, and pressure of business, he, in order to fill his orders promptly, sent me *tested* queens—a method of fair, honorable dealing, for which, I have since learned, Mr. Hayhurst has achieved a well-deserved reputation. From those 5 lbs. I increased to 10 strong colonies, practically 13, for I caught a swarm of hybrids in the country, which I divided into three colonies, and Italianized from my Hayhurst bees. At first, recreation and a change from the routine of indoor labor was the object sought; but in spite of every thing, I caught the fever; and should I lose my bees this winter, the probabilities are I shall be convalescent in the spring, but not absolutely *cured*. In August I bought of W. M. Scheidall 43 stocks and all his apiarian supplies, consisting of prize boxes, 8000, mostly in flat; 300 frames for prize boxes, honey-extractor, A B C of Bee Culture, GLEANINGS since 1879, Simplicity hives sufficient to increase my apiary to 200 single boxes. Thus you see I have at this writing 56 colonies. If this isn't bee-fever on short notice, Mr. Root, then what would you call it?

Eureka, Ill., Dec. 30, 1885. S. W. LAKIN.

FROM 50 TO 66, AND 2000 LBS. OF HONEY, BY ONE WHO IS 74 YEARS OLD.

I take GLEANINGS, and am very much interested in reports. I am 74 years old, and have been in the bee-business more or less since I was 18 years old. I took out of my cellar last spring 50 stands of bees in good order. Notwithstanding the poor season, I took over 2000 lbs. of extracted honey, and put back this fall 66 stands, strong and in good condition. I have never raised section honey, but I think of doing so now, as I have given up other business, and will have more time for my bees.

Cascade, Ia., Dec. 30, 1885. WM. HEITCHEN.

FROM 31 TO 54, AND 1200 LBS. OF HONEY.

Bees did better here last year than usual. I began the spring with 31, and closed in the fall with 54. I have already moved most of my bees, and will move the rest soon to the Dugdown Mountain.

We got last year about 1200 lbs. of honey, increased 23 swarms, and sold 3 besides. Most of the honey was extracted, and was sold at 12½ to 15 cts. per lb. We have on hand at this date, about 15 gallons. Some of our colonies are weak, but I think we shall be able to begin the spring (say first of April) with 45. We expect our bees to do better this year, as we think we have a better location. The Dugdown is a part of the Appalachian range of mountains, beginning in Alabama, and extending to the mouth of the St. Lawrence River. We are now at the foot of this range (north of it), so that our bees will have access to the forests on one side, and the fields on the other. J. M. HARRIS.

Cedartown, Polk Co., Ga., Feb. 13, 1886.

FROM 37 TO 95, AND ONE TON OF HONEY.

I now have 95 swarms in the cellar, and they seem to be feeling first rate, by their appearance, this cold winter weather. I increased from 37, spring count, to 95, and secured a ton of salable honey. I could have done much better, but I was alone, and had all to do as far as attending to the bees was concerned. My wife made nearly 1200 honey-boxes, and helped about extracting some 300 lbs. We extracted only to give the queen more room. We are somewhat advanced in years, my wife being 53, myself 58. H. F. NEWTON.

Whitney's Crossing, All. Co., N. Y., Jan. 20, 1886.

FIRST PREMIUM FOR THE BEST DISPLAY OF HONEY AT THE NEW ORLEANS EXPOSITION, BY A "NOVICE."

At our State Fair, held at this place last Oct., I received a diploma for "best display of honey." I sent a few sections to New Orleans, and have just received a diploma from there for display of "very fine honey," and I feel very much pleased for a "novice" in the business. I have not made much money as yet, but am still pushing along, and I think that, after this season, I shall be able to hold my own. E. A. MOORE.

Reno, Nevada, Apr. 15, 1886.

THE ENORMOUS YIELDS OF ONE COLONY.

The past honey season in this vicinity was the best I have known since I commenced keeping bees, ten years ago. It is the first season I have been able to obtain any surplus from the willow. Some of my best swarms gave me 20 to 25 lbs. of willow honey in sections. The season throughout was very favorable. From my best swarm I extracted 360 lbs., mostly clover; this was from one swarm only, no increase. I ran them this season 6 stories high, L. hive (winter them in three stories). I think I could have taken 400 lbs. from that swarm if I had had help to extract at the proper time. Last season they gave me only 45 lbs. The two seasons previous, that hive gave me 340 lbs. each year (1882-'83); in 1881 it gave me 310. The honey for 1882-'83 (640 lbs.) I sold for $136. That hive has paid the best of any I ever owned. Somehow I have not been able to obtain nearly that amount from any other hive. They seem to have the "push" to them, and work with more vim than any other swarm in my yard.

I wish to say a word in favor of the perforated-zinc honey-boards. They work to a charm with me. I would not be without them for twice their cost; no trouble now in obtaining frames solid full of honey in the supers. I shall use them largely the coming season. CLARENDON BUTMAN.

Plymouth, Maine, Jan. 25, 1886.

HEADS OF GRAIN
FROM DIFFERENT FIELDS.

A SMOKER NOT ALWAYS NECESSARY; ALSO A KIND WORD FOR THE EDITOR OF GLEANINGS.

FRIEND ROOT:—I believe you a friend to every "beeist," therefore I hope I am not unduly familiar in addressing you as "friend Root" on such short acquaintance. The impression your editorial and comments therein have left on my mind are that you are "full of the milk of human kindness," and that I need not be so formal in writing you.

My first experience in bee-keeping began last spring, when I bought three strong hives of Italians. During the season they increased to ten (including one swarm that "took to the woods"). I sold three hives and a little honey, and started the coming season with six strong colonies that have been left just where they were first placed, and have required no feeding or other attention so far, and I think they will come through all right.

I want to give you a bit of my experience with the smoker which I got from you. It was a little late in the season when it arrived, and I had safely hived my three first swarms without getting a sting, and I used neither smoke, gloves, nor veil; but when my smoker did come, I thought I'd show them that I was "big Ike," and let them know what was in store for them if they didn't behave. So I loaded up the smoker, went out to one of the hives, and lifted off the top, with a sense of *authority* and *security* that must have tickled them immensely, for it wasn't more than ten seconds after when I gave them their first dose of smoke before they began to "tickle" me in a way that was not at all funny to me, however much they may have appreciated it. Since then I use smoke only when I'm obliged to, and I find that, by careful, gentle handling, I seldom require it. WM. E. CUNNINGHAM.

Hartwell, Hart Co., Ga., Feb. 22, 1886.

Friend C., you have hit upon an important truth. A great many times bees behave worse with smoke than without it; and it is the business of the intelligent bee-keeper to tell when to use it and when not to use it.

MEXICAN BEES, IN APPEARANCE LIKE AN ITALIAN QUEEN.

I saw in one of the back numbers of GLEANINGS where Mr. McCamant speaks of Mexican bees. One of my friends told me of cutting a bee-tree up in the Nueces Cañon. He said the bees were yellow, and longer than the blacks. I supposed at the time they were Italians; but the other day another of my friends who had worked with bees a good deal told me of robbing a cave up there, and that the bees were long and yellow. They were very gentle, and did not sting him once. I questioned him closely in regard to them, and showed him my Italians—also a queen. He said they were all like the queen I showed him. Next summer we are going up there to see if they are really as he describes; and if I do I will send you a few of the bees. W. B. KENDALL.

Uvalde, Tex.

Friend K., by all means look this matter up. If we have native bees in our own land, with yellow stripes on, we all want to know it.

POISONOUS HONEY OF ASIA MINOR.

From an article on honey, in the Library of Universal Knowledge, I note the following:

> It should be mentioned, that honey occasionally possesses very deleterious properties. Xenophon, in his history of the Retreat of the Ten Thousand, describes the honey of Trebizond as having produced the effect of temporary madness, or, rather, drunkenness, on the whole army who ate it. Mr. Abbott, writing from Trebizond in 1833, to the secretary of the Zoological Society, observes that he has himself witnessed that the effects of this honey are still precisely the same as those which Xenophon describes, and he adopts the views propounded by Tournefort in 1704, that the poisonous properties are consequent on the bees extracting the honey from the *Azalea Portica*. Many other instances of poisonous honey are on record.

From an article on the *Azalea* (same authority), I note:

> The whole is narcotic and poisonous, and the honey collected by bees from its flowers, which very much abound in honey, is said to cause stupefaction and delirium.—North America abounds in azaleas.

Dresden, Tenn., Jan. 23, 1886. GEO. S. BOYD.

CAN THE WORKER-BEES CONTROL THE SEX OF EGGS?

Two years ago, on taking bees out of my cellar, I found one queenless colony, and I gave them a frame filled with worker-eggs, no drone-cells in the comb. On examining, after some days, I found several queen-cells, and a patch of drone-cells about 3 inches square, from which perfect drones were hatched. Does not that prove that the workers have the power of controlling the sex of the egg? I think it is conclusive proof that they can, and do so when circumstances render it necessary for them to exercise that power. J. BLACKHALL.

Hobart, Ind., Mar. 26, 1886.

WHAT KILLED MY BEES?

There is nothing in bee-keeping that is more annoying than robbing. I have had several cases of it since I began, three or four years ago, and in every case it was brought about by some oversight or negligence on my part. I had a case during the winter; and from the confidence with which "sheeting" is recommended I unhesitatingly applied the sheet to the robbed colony. The result was a considerable loss of bees that at nightfall were found adhering to the sheet, unable to fly. In addition there were quite a number in the same condition on the ground under the sheet. I concluded that, warm as was the day for winter in latitude 32°, it was too cold for a prolonged stay of the bees out of the hives. But having another robbing case this spring, and again applying the sheet, the loss of bees was still more striking. In putting on the sheet, which was quite large, I took particular pains to stretch it as far away from the hive as possible, so that there might be no lack of fresh air to the imprisoned bees. The result was the death of hundreds of bees. As I did not wish to have my bees destroyed in such a way, I confined them next day to the hive by means of a wire-cloth covering over the entrance. This seems to have worked nicely, as I was very careful to shield the hive from the rays of the sun, and at night to give them a small pan of water, every drop of which they drank. Now, in the sheeting cases, what killed my bees? I confess that I am utterly in the dark. JOSEPHO.

Tuscaloosa, Ala.

Friend J., didn't the bees sting each other while confined under the sheet? Robbing usually results in the death of a good many bees, no matter how it is managed. By far the better way is to have the colonies and entrances so arranged that no robbing ever gets started, even for a few moments.

HURTING THE HONEY-TRADE.

I am compelled to bring my pen into use now, as I have read Mrs. Harrison's and Mr. George A. Wright's letters in Feb. 1st GLEANINGS, pages 97, 98. I could not help saying amen when both strike the key-note on feeding honey in place of sugar. Theirs have been my thoughts for two years, but I would not say a word to you about it, for fear you would just give me "hakins" because you recommended feeding sugar so much. A bee-friend of mine some four years ago fed sugar, costing him 10 cts. per lb., and sold the same at 15 to 20 cts., and was caught at it, and that little bit of transaction has damaged the honey-trade in this place to such an extent that it will take years to get rid of the idea that all honey brought into market by bee-men is more or less sugar. But old box-hive farmers have pure honey, as they have not learned to feed sugar. Why, one of our grocerymen asked me one day where I bought my sugar to feed so many bees—100 colonies. What I say is, Let the bees die if they do not raise enough to live on. I, too, feed section honey, if I have not enough other. The time has come for bee-men to stop helping the sugar-trade to our detriment. WILLIAM ST. MARTZ.

Martinsville, Ill., Feb. 3, 1886.

EFFECT OF REDUCING THE SIZE OF THE ENAMEL CLOTH OVER THE BROOD-NEST.

I notice in a recent issue of GLEANINGS that an inquiry is made by a correspondent in regard to the use of enamel cloth over the brood-chamber, the same cut somewhat smaller than the hive. Your reply, that it would not be practicable unless slits were cut in it, is directly opposite to what my experience has been for the past two years. I cut my cloth about two or three inches smaller than the hive, so the space left uncovered is, of course, from one to 1½ inches wide. I have had no trouble from the queen, and I think sections are cleaner than when no cloth is used. I think it very unlikely that a bee heavily laden would make her way over the brood-combs, covered as they are by bees, but she would take a more unobstructed passage up the sides of the hive and outside ends and side of the frames. If this be so, the cloth might come within ½ inch of side of hive, and not be any obstruction to them.

Another advantage of the cloth is, that a strong draft is prevented through the brood-nest when operating with the sections, and the bees are not excited to the extent they are without it.

Rochdale, Mass., March 1, 1886. J. R. NICHOK.

THE BEE MOTH.

It has been discovered beyond a doubt, that the bee moth follow civilization. We emigrated from Lake Co., Ohio, in May, 1844, and landed at Milwaukee, Wis., then quite a flourishing village. We moved up by land to Sheboygan Co., on the old military road, cut through the wilderness by the government. The upper lake counties being all timbered lands, we found that the woods in the western part of Sheboygan Co. abounded in wild bees in trees. There were no signs of the bee moth. We found some trees where the bee-comb was so old and black that the honey-cells were not one-half size. The comb was heavy; we could not strain out the honey, so we boiled it out and then boiled it down and clarified it the same as maple syrup. The bee moth did not appear until the 7th year among the domesticated bees. The wild honey-bees were far in advance of settlers in Wisconsin and Minnesota.

HOW BEES EMIGRATE?

A bee-hunter saw a swarm going in Illinois in the direction of a grove that was 15 miles distant, being the nearest timber. On arriving there he was told by a settler that they had gone over; and the direction they went from the grove, it was 30 miles to the next timber. During the war, when the 4th Wisconsin Volunteers were in route from Fortress Monroe to New Orleans, and when off the coast of Florida, a swarm of bees went through the rigging, going seaward. There was some speculation among the officers and men as to where the bees would hang up at night, etc., as they must be Union bees, flying from the land of secession, being invariably robbed by both armies; they passed over about 11 o'clock A. M., going in the direction of Cuba.

Chetek, Wis., Feb. 18, 1886. E. G. SLAYTON.

LEAVING ON THE UPPER STORIES DURING WINTER; FRIEND FRANCE'S IDEAS UPON THE SAME.

On page 104 of Feb. GLEANINGS I find an article entitled, "Danger of Leaving an Upper Story on During Winter." Mr. J. W. Thompson says he has lost one colony, and charges the loss to the bees having all sealed honey. He says, "So you see the loss of this colony is attributable to my neglect, for I knew very well that bees could not winter, even in this climate, on all sealed honey." And the editor, in his foot-notes, doesn't help the case at all. He says, "Bees are always liable to go into the upper story when it is left on all winter, because the warmth from their bodies rises naturally, and they follow in their efforts to cluster in the warmest place in the hive."

Now, I disagree with Mr. Thompson, that bees can not winter on all sealed honey. Allow me to say a few words, as I have had a large experience in wintering bees outdoors. If Mr. T. had put that set of all-sealed honey into the upper story, and his empty combs in the lower story, his bees would not have starved. I am wintering 60 colonies in L. hives, all with upper stories on, and my aim was to have the upper story full of good sealed honey. I have the lower story full of combs, and have enough of the lower combs empty for the bees to cluster in during wet weather. When the weather is very cold, the bees crawl into the combs, one bee in each cell, and then fill the spaces between the combs with bees, making a solid ball of bees. If their stores are over the bees, they will get it, as the heat of the bees rises, but they won't cluster up among the full combs of honey in cold weather. As they could occupy only the spaces between the combs, and could not keep themselves and the honey warm, they cluster up as near the honey as they can, and will follow the honey up as they eat it out.

A good strong colony, with empty combs to cluster in, and honey enough over the cluster so they don't eat their way up through to the top of their honey, will stand a great deal of cold weather, and come out all right in the spring.

My L. hives are all made quadruple chaff hives. I have used them four years, and have had good success wintering outdoors. E. FRANCE.

Platteville, Wis., Feb. 15, 1883.

FACTS VERSUS THEORIES, AND THE PROMPT WAY IN WHICH FRIEND BROERS OBEYS ORDERS.

I notice you say in GLEANINGS, April 1, that you want us bee-keepers to give you facts from experience, not opinions. Now, I have to-day had some little experience which has taught me one fact which I will try to remember; and as others may have similar experience, only it might turn out worse than mine, I will give the facts here, so that others may profit thereby. To begin, I had a rousing swarm of bees come out about 9 o'clock, April 3, which were duly hived, and are doing well at this writing. Yesterday I noticed that a great number of young though seemingly mature bees were crawling out of the parent hive above mentioned, and were dropping in a helpless condition in front of the hive. I felt suspicious, but let them alone until this morning, when I opened the hive and found the bees were actually starving. I at first thought it might be something else; but to test the matter, I tilted the hive back and poured in about a gill of sugar syrup, and in less than half an hour every thing was lovely again, and they have been working all the rest of the day. By way of explanation, I must state that, the night after the swarm came out, there came a north wind which blew for three days, and, of course, checked the honey-flow completely, as we came near having frost; in fact, we did have a little, but it did no great damage. I could give you my opinion about the matter, but that would be contrary to orders, so I give you the facts, and should like to have your opinion. I have never heard of a similar case; and if I had not been on the lookout, I should have lost a good colony of bees; therefore I give the above as a caution to others. I have had six swarms up to date—41 colonies, 5 nuclei on hand.

Gonzales, Texas, April 8, 1886. M. BROERS.

Very good, friend B.; and the moral to your little story is so plain I think we can all "catch on," even if you don't give us your views.

OVER $500 WORTH OF GOODS OF US—ALWAYS SATISFACTORY.

I have just received a draft for honey and wax sent you. I am very thankful to you for helping me out on honey. I have sold only $500 or $600 this season, about one-third as much as usual; price 10 and 12½ cts. for extracted, and 12 ½ and 15 cts. for comb. I have been looking over our accounts since I began bee-keeping with four swarms in 1878, and find I have purchased of you over $500 worth of goods, and your goods have always given satisfaction. I now have 70 chaff hives, with metal-cornered wired frames for all of them. I would not use any other frame. I am very particular to have the wires imbedded in the frame, as it is less bother with propolis. I like the plan of filling the upper tier of wide frames with closed-top sections, as it is less work to clean them. After having a good many sections built wholly on one side, and others stuck to tins, I am particular to have the frames and boxes stored perpendicularly instead of down flat, as I used to. The red-clover queens I got of you have always given good results. Nearly every Italian swarm gathered enough honey to winter on, while the few blacks I have had to be fed from 5 to 20 lbs., and there has always been about the same difference every year.

What has given me more pleasure than your square dealing, and the interesting varied departments of GLEANINGS, with your sound views on tobacco, and all other evils, is the education of your children for honorable productive industry, instead of making aristocratic nobodies of them.

CLAUDE SMITH.

Norwich, Chenango Co., N. Y., Mar. 11, 1886.

IODINE AS A REMEDY FOR BEE-STINGS.

Noticing your remarks in A B C book concerning remedies for bee-stings, let me relate: For many years I have obtained a precarious livelihood by the practice of medicine. I once had several swarms of bees, and read "Langstroth on the Honey-Bee." Of course, I got stung. Now, a bee-sting is with me a rather serious matter. One in the fall will close my eyes (one or both) for two days. When attending medical college, Prof. Brainerd demonstrated to us the control of iodine over the "woorah" poison, and gave his opinion that the poison of serpents and of venomous insects is nearly or quite identical. I tried tincture of iodine on the bee-stings, with complete success. If applied before the poison has time to get beyond its reach, it (on me) relieves the pain *instantly*, and prevents the subsequent swelling. Let "the boys" try it; and if it proves a success, publish it in some bee-journal as a small contribution to the relief of one of the ills to which humanity is liable.

O. B. ORMSBY, M. D.

Murphysboro, Ill., Apr. 4, 1886.

Friend O., your remedy has been given several times in the pages of GLEANINGS; but as it has been dropped after a time, and apparently forgotten, I can not think that it as a general thing makes any very great difference. If the remedy can be made to reach the liquid poison, no doubt it might neutralize it.

GROWING LINDEN FROM SEED, NOT ADVISABLE.

In response to some inquiries in regard to raising basswood, or linden, from the seed, the proprietors of the Elgin nurseries answer as follows:

In reply we will say, that we do not think it would be advisable to recommend growing the linden from seed or layers; those who do not understand it would only make a failure of it; and if they wanted only one or two thousand trees they would spend more time and money than it would cost to buy the trees one or two years old; and nine out of ten would have nothing to show for their bother and cost of seed. If you want us to grow linden for you on a contract, we can grow them very cheaply—much cheaper than any one can afford to grow them where only a few are wanted. The above is the most sensible thing we can give you on linden, as you want them.

Elgin, Ill., Mar. 13, 1886. E. H. RICKER & CO.

EUROPEAN AND OTHER LINDENS; SOME VALUABLE FACTS.

I wish to state that the European linden (*Tilia Europæa*) has not so large a leaf, nor is it so rapid a grower, as the American, but forms a more compact head, or crown. The same may be said of *T. macrophylla*. There is, however, a serious drawback to the European forms; during our hot and dry seasons, when they are often denuded of all leaves for a long time till the moist season sets in, a small after-growth is produced, which is not always conducive to a healthy state. The so-called silver-leafed linden (*heterophylla*) is a native, often found among others. Pretty large trees can be transplanted, in cities and villages, where maples, elms, etc., fail. I have succeeded with linden, and plane-tree, or buttonwood. F. Z. M. OTTO.

Sandusky, O., Mar. 7, 1886.

BAREHEADED BEES NOT CAUSED BY WAX-WORMS.

I noticed in GLEANINGS some time ago, where C. C. Miller says: "Now, I don't quite think they ever leave them uncovered till the wax-worm uncovers them, or runs a gallery over the bees in the cells for the bees to dig away, thus leaving the cells uncovered," and he also puts the query to you, "Did you ever see a patch so large that you could lay a silver dollar upon it and have all the cells under it uncovered?"

Now, friend R., I have read the statement referred to by friend M. in the A B C, and have made it a point to verify it; and I can say positively that I have seen strong colonies of bees, in hives perfectly free of worms, that left patches of brood bareheaded, as you term it, that you could not cover with *two* silver dollars, and old enough to begin to assume the natural color of a bee when mature. Our warm climate may have something to do with the matter, but what I tell you I *know* to be a fact.

Gonzales, Texas. M. BROERS.

HOUSE-APIARIES — DIFFICULTIES OBVIATED IN PART.

In your remarks on friend Clarke's article you say you would want no floor. How would you make it mouse-proof? My house is mouse-proof, also bee and moth excluding. When moths undertake to get in they only get under the outside doors, on to the screen-doors, and are easily killed in the morning. My house does not heat up, as friend Clarke says. The screen-doors admit a circulation of air, they being the only ones used in hot or warm weather, except that the outside doors are closed nights. I think the reason bees do not go out at those little doors, as you mention, is because such a draft of air comes in so strong as to almost take the little fellows back, and the air is cool too. There should be no windows, as the sun shining on them causes much more heat, and they bother getting the bees out of the house, while screen-doors do not.

H. S. HOXIE.

Holloway, Lenawee Co., Mich., Mar. 8, 1886.

Friend H., I would get rid of the mice by using "rough on rats." We have of late, and find that it is cheaper than cats or any thing else, and it does the business effectively.

A FEW MORE PROOFS THAT DRONES DO CONGREGATE IN LARGE NUMBERS.

On page 259, O. G. Russell strikes the right key where he says, "I believe that drones congregate in large numbers, and the queen, attracted by their loud humming, flies among them and is fertilized." We have large red ants here that live in the ground, make a mound, and carry seeds to live on (agriculturists). The queens and drones have *wings*. I have seen the spot three seasons where the queens were fertilized. The air is full of drones and queens, and they fall to the ground clutched together. I have seen several drones holding to one queen. I have noticed drones from my hives all going in the same direction. My neighbor, living over four miles away, keeps black bees. One season I noticed my drones going south-east, and afterward we noticed he had Italian bees. I have thought for ten years that the drones selected a spot, and that the queens congregated there by the humming of the drones. I should like to hear more on the subject. I think the spot can be found by lining the drones.

Sherman, Texas, Apr. 8, 1886. M. S. KLUM.

EUROPEAN LINDEN INFERIOR TO AMERICAN.

Having just received GLEANINGS, I see that you ask if there is any one who could tell about how much honey the blossom from the European linden would produce, compared with the American. I don't know that I am competent to explain it clearly. I was born in Switzerland, and emigrated to America in 1870. I was then 20 years old. I have gathered linden-blossoms there, as they use them for tea in some kinds of sickness. The blossoms are about half as large as they are in American linden and are not as plentiful as on American linden either. I am taking a county paper from home, and see that a bee-keeper gives his report for 1885, the person being a minister of the gospel. He had 60 colonies in spring, and obtained 2800 lbs. of honey. He sold it for 2800 francs. He considered the season one of the best they have had there for many years. H. WIRTH.

Borodino, N. Y., Feb. 20, 1886.

Thank you for the valuable information you furnish in regard to the European linden, friend W. Very likely our American is the best for honey.

A QUERY IN REGARD TO MAKING FOUNDATION.

The foundation-mill came to hand in good order. The charges on both packages were but 90 cents, which I think was very reasonable. Now one question: Do you ever use water in the center can? If not, how do you get the wax out when it gets partly out, and you have no more with which to fill?

Bees are wintering well. I suppose almost every bee-keeper is trying to accomplish something unusual, either in wintering or something else, and I am no exception.

WINTERING A SWARM ON ONE EMPTY COMB.

On the 29th of November last I took a small late swarm, without a particle of honey, and gave them one empty comb to cluster in, or so that the queen could start brood whenever she saw fit. I placed this comb with the bees between two of my patent feeders, filled with food enough to winter a small swarm. I have not had the feeders patented yet; but as it is getting to be fashionable to patent hives and fixings in Michigan, I don't know but I shall have to follow the fashion. On the first of December I put this swarm, with the rest of my bees, into my bee-cellar. The fifth of March I took all my bees out for a fly. You can imagine about how I felt when I found this little swarm in as nice condition as though they had been wintered on a hive full of honey or any other kind of food.

Now, friend Root, I know that one swallow does not make a summer; I also know that one straw will show which way the wind blows. Another winter, if I live, and my bees live, there will be more than one swarm fixed for winter just the same as this swarm was. The feed will cost from 75 cts. to a dollar per swarm. A man can make and fill feeders enough for ten or fifteen swarms in a day. You have no bother feeding, besides saving all the honey. But, wait a moment. I said one swallow does not make a summer. I have just been out and examined this swarm. They have a nice patch of brood, and one of the feeders is about one-third filled with nice new comb, as white as paper; and as the top-bar of the feeder is the top-bar of an L. frame, or, rather, the feeder is an L. frame with my—well, my patented sides nailed on, all you have to do is to take the sides off and you have a nice comb all ready for the queen, and I am not sure but if I had looked closely I should have found brood in this comb. WM. L. KING.

Sodus, Berrien Co., Mich., Mar. 10, 1886.

The matter of using water under the melted wax, in making foundation, has been frequently discussed. We do not use it in our work, because we always have plenty of wax; but many of the friends say they succeed just as well with water under the wax. —The matter of wintering a colony on empty combs is not new. The same thing has been done repeatedly, with nothing but lumps of candy laid on top of the empty combs.

BOOKS ON ENGINES AND STEAM-BOILERS; WHERE TO GET.

I notice in GLEANINGS, Mar. 1, that V. W. Keeney, of Shirland, Ill., wishes to get a work on the steam-engine. I will say to him that he may procure the work he wants from "Frederick Keppy, Bridgeport, Conn." Send him a stamp for his catalogue. His books are fully up to the times. The following books of his publication, best adapted for stationary engines, are, "Use and Abuse of the Steam-Boiler." Price $2.00; and "Practical Steam-Engineer's Guide," price $2.50, postage paid. I think you will do well to add the above two works to your book-list. The time is coming when engineers will be required to have a thorough knowledge of the duties they are called upon to perform.

Luna, Ark., Mar. 1, 1886. E. H. SMITH.

CAN PURE GRANULATED HONEY BE SUCCESSFULLY IMITATED?

In all I have read about honey since I became a bee-keeper, I do not remember of any one claiming or suspecting that pure granulated honey could be successfully imitated, except friend Foster. If I remember rightly, you did not agree with him, Mr. Editor. Now, if you regard pure granulated honey as difficult, or not likely to be imitated, why not advise the friend on page 184 to purchase granulated honey? Very many of us claim its imitation is impossible, and state this to dealers and consumers. I wish to know whether this is true or not.

J. B. COLTON.

Waverly, Bremer Co., Ia , Mar. 8, 1885.

I have never seen a successful imitation of granulated honey, friend C. The granulation of grape sugar might, at first glance, be considered the same thing; but careful investigation will show that it is not granulation at all. It is simply solidification, just as tallow gets hard by cooling.

WHAT IS THE BEST METHOD OF MANAGING THE CLUSTERING OF SWARMS IN A FOREST?

I write to you for advice as to how to manage our bees. We work for section and comb honey mostly, and some extracted. We have managed by natural swarming, putting swarm No. 2 into hive No. 1, swarm No. 3 into hive No. 2, and so on. We get plenty of honey sometimes, but it takes much hard work, for we live in the timber, and are surrounded by forest-trees. Many swarms alight 25 to 30 feet high, and I have to move a heavy ladder and climb after them. As I am 57 years old I do not see much romance in it. The bees swarm out a good deal, and thus make us more work. If you give us some easier way, we shall be much obliged. We have the A B C book (old), about one bushel of GLEANINGS, and over 80 swarms of bees in Simplicity hives. We use division-boards, and pack in chaff by setting a rough box over the hive, filling in, and covering over with about 4 inches of chaff. We put this on in the fall, and take it off about the first of June. We use the hives two and three stories high in summer, taking them off in the fall, and wintering in the lower stories. I have been very successful in wintering without loss, and my bees come through pretty strong too. We do not make it pay financially. I like to work with the bees pretty well, but my women-folks do not care much about it. Our two oldest girls have gone to Washington Territory, and that will leave us short of help. There is very little sale for bees here.

E. A. KIRKPATRICK.

Bowling Green, Pike Co., Mo., Feb. 10, 1886.

Friend K., this matter of keeping bees from going into the tops of high trees to cluster has been a good deal discussed; but it seems to me that no better way has ever been offered than to have the apiary located where such large trees are not very near by. Swarming artificially, so as to keep the bees from natural swarming as much as possible, is also a remedy.

ONE BUCKET OF WATER DAILY FOR THE BEES.
